PREFACE

The work programme of the ECLAC/CELADE Demography Unit emphasises the implementation of activities aimed at developing and strengthening national and regional capacities for integration of population considerations in development planning and for population policy formulation and implementation. This is being accomplished through the adoption of a multi-pronged approach initiating activities, at governments' request, in the following areas: research, data generation and evaluation, training, population policy formulation and implementation and information, education and communication activities.

The building of a central store of data and the evaluation of its quality constitute an essential component of the population-development integration process, as planners and policy-makers need to have confidence in the data being utilized. A number of programmes have therefore been developed with the aim of improving the quality and quantity of socio-demographic data - one of the basic inputs in development plans.

The present exercise in population projections for the eight Caribbean countries represents such a programme and is a follow-up to the ECLAC/CELADE Training Seminar in Population Projections held in Port of Spain, 28 April - 7 May 1986. Participants comprised representatives from nine Caribbean countries - Belize, the British Virgin Islands, the Commonwealth of Dominica, the Commonwealth of Grenada, Montserrat, Saint Christopher and Nevis, Saint Lucia, Saint Vincent and the Grenadines and the Republic of Trinidad and Tobago.

During this seminar, preliminary analyses were made of trends in the components of population growth for each country - fertility, mortality and migration. Data for the period 1960-1985 were reviewed, while graphs, tables, and other analytical tools were developed. Finally, the first drafts of population projections were developed by each participant for their own country.

The current set of projections represents a refinement of the output from the seminar and includes further census data evaluation, adjustments of data, development of alternative scenarios and refinement of assumptions. The study is in two parts:

Part One consists of a preliminary report prepared by Barbara Boland and Javier Perez Astorga which discusses the base data and the methodology and assumptions used in the projections.

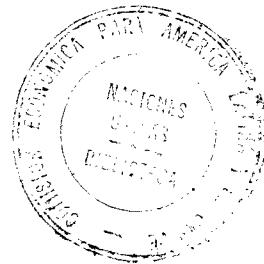

Part Two contains an analysis of the results by Jack Harewood. The projections were prepared by Desmond Hunte and George Sellu under the general direction of Barbara Boland and Jack Harewood.

It is hoped that the results will provide planners and policy-makers with data for use in future planning, and assist in furnishing them with sufficient 'lead time' to prepare for coming needs in terms of social and economic programmes.

Finally, the assistance of the United Nations Population Fund (UNFPA) in providing funding for the study and this publication through the UNFPA/ECLAC regional project "Integration of Population in Development Planning" is gratefully acknowledged.

PART ONE

DATA, METHODOLOGY AND ASSUMPTIONS

INTRODUCTION

The basic data utilized as inputs into the projection exercise are vital statistics and census.

With regards to the vital statistics, as noted in the earlier report on the "Population Projections Seminar"¹ May 1986, an evaluation had already been conducted in 1985 through the UNFPA funded project titled "Training in Demographic Analysis"²

The general findings were that the vital registration data for eight english-speaking countries of the region were of fairly high quality. As a result, it was not considered necessary to carry out any further evaluation of that data. Instead, emphasis was placed on the analysis of census data.

A. ANALYSIS OF CENSUS DATA

Measurement of Age-accuracy - United Nations Index

An attempt was made to measure the age-accuracy of the census data using the United Nations Index³. The latter consists of the computation of sex-ratios and age-ratios for five-year groups of ages, up to age 70. In the case of sex-ratios, successive differences between one age group and the next were noted, and their average taken, irrespective of signs. For age-ratios of either sex, deviations from 100 were noted and averaged irrespective of sign. Three times the average of sex-ratio differences were then added to the two averages of deviations of age-ratios from 100, to compute the index.

It is to be noted that this index is affected by irregularities arising in certain age-groups as a result of migratory movements.

¹See "Report on Population Projections Training Seminar" - ECLAC/CELADE, August 1986.

²See "Report on Training in Demographic Analysis Project" - ECLAC/CELADE, December 1985.

³United Nations "Methods of Appraisal of Quality of Basic Data for Population Estimates", Manual II.

The results obtained for all countries are as follows:

TABLE 1
MEASUREMENT OF AGE-ACCURACY- UNITED NATIONS INDEX

Country	Index
Belize	22
The British Virgin islands	75
Dominica	33
Grenada	32
Montserrat	51
Saint Christopher and Nevis	41
Saint Lucia	27
Saint Vincent and The Grenadines	34

A general classification⁴was developed to interpret these index values as follows:

- More than 40: Deficient Information.
Between 20 and 40: Data of Intermediate quality.
Less than 20: Satisfactory data.

As can be seen, the quality of data for most of the countries falls within the range of "intermediate quality", (despite the effects of migration on the age-sex structure). Thus, it was considered unnecessary to carry out any further adjustments to the age structure. Two countries, the British Virgin Islands and Montserrat, proved to be the main exceptions, possibly as a result of their very small size which renders the age structure extra sensitive to migratory impacts.

⁴Chackiel, J. and Maccio, G., "Evaluación y corrección de Datos Demográficos", No. 6, 1978, CELADE, Chile.

Sex-Ratio by Age

With regards to the sex-ratios by age, certain inconsistencies were found. However, it could be argued that these irregularities can be attributed, in large part, to the impact of heavy migration in the region⁵. Further analysis revealed that these movements were not uniform by age and sex. This is clearly illustrated in the structure of survival ratios calculated from the 1970 and 1980 census data. (See also age-sex pyramids in projection reports for individual countries).

Cohort Differences

An estimate was made of the differences in cohorts between the two censuses 1970 and 1980. For this purpose, ten-year census survival ratios were estimated and the absolute cohort differences compared. Some irregularities were observed among certain age groups. Since the census data of most countries is considered of good quality, these differences could be largely attributed to the impact of migration which does not exert a uniform effect on all age groups.

B. PROJECTION BASE POPULATION

The 1980 census was used as the base population. In the case of some countries (Saint Vincent and the Grenadines, Saint Lucia and Belize) the officially adjusted census was used. Each census population was carried forward to the mid-year (30 June) using the growth rate of 1970 - 1980. In the case of the two countries, in which the census was taken in 1981, Grenada and Dominica, the census population was moved backwards to mid-year 1980.

C. PROJECTION OF MORTALITY

Mortality

The health conditions in the countries have improved tremendously over the past two decades as illustrated in the high expectation of life at birth, ranging from 63 to 71 years for males and 67 to 75 years for females.

⁵See Guengant, Jean-Pierre and Marshall, D. Caribbean Population Dynamics: Emigration and Fertility Changes". Letchworth Press, Barbados, 1985.

Life Tables

Life tables were constructed for 1970 and 1980 using the Reed-Merrell method and compared with those constructed earlier by ISER, UWI, at the ECLAC/CELADE Projections Seminar in May 1986. As little differences were found between the life tables (small variations due to differences in methods used to smooth the nqx curve), it was decided to retain those developed at the Projections Training course for most countries. However, some adjustments had to be made to the survival ratios.

Mortality Projections

Future trends in mortality were estimated through the projection of the level of expectation of life at birth for each period. Instead of adopting a linear rate of increase in the evolution of expectation of life, a logistic model which assumes that mortality will increase according to an asymptotic curve, the expectation of life at birth is projected for each five-year period of the projection according to the following formula:

$$Y_t = K_1 + \frac{K_2}{1+e^{a+bt}}$$

Where:

K_1 = the lowest asymptote

K_1+K_2 = the highest asymptote

$a + b$ = parameters

In developing these projections, the following principles were considered:

- (i) that the expectation of life at birth increases with time;
- (ii) that the difference between sexes grows wider over time; and
- (iii) that the rate of gain in life expectancy diminishes over time.

However, for some countries, it was not always possible to adhere strictly by these principles, given the past trends in their mortality experience which often indicated certain deviations from the standard mortality behaviour. A projection of life expectation at birth is presented in Table 1.1.

TABLE 1.1
PROJECTION OF EXPECTATION OF LIFE AT BIRTH
BY SEX FOR EACH QUINQUENNIUM PERIOD

Country	Expectation of life at birth						
	1980- 1985	1985- 1990	1990- 1995	1995- 2000	2000- 2005	2005- 2010	2010- 2015
<hr/>							
Belize							
Males	70.38	71.08	71.67	72.19	72.62	73.00	73.31
Females	72.60	73.37	74.04	74.62	75.12	75.55	75.92
British Virgin Islands							
Males	65.45	66.41	67.24	67.96	68.58	69.12	69.57
Females	73.33	74.66	75.64	76.34	76.83	77.19	77.43
Dominica							
Males	62.81	63.54	64.19	64.80	65.37	65.90	66.38
Females	67.93	69.82	71.42	72.75	73.84	74.72	75.42
Grenada							
Males	66.73	67.75	68.66	69.44	70.13	70.71	71.22
Females	73.03	74.34	75.23	75.83	76.23	76.50	76.73
Montserrat							
Males	62.81	63.54	64.19	64.80	65.37	65.90	66.38
Females	67.93	69.82	71.42	72.75	73.84	74.72	75.42
Saint Christopher and Nevis							
Males	62.81	63.54	64.19	64.80	65.37	65.90	66.38
Females	67.93	69.82	71.42	72.75	73.84	74.72	75.42
Saint Lucia							
Males	67.00	67.87	68.56	69.11	69.54	69.87	70.13
Females	72.57	73.71	74.56	75.21	75.69	76.04	76.30
Saint Vincent and the Grenadines							
Males	65.62	66.84	67.85	68.69	69.37	69.93	70.38
Females	70.87	72.18	73.28	74.18	74.92	75.52	76.01

After the projection of the levels of mortality was completed, the age structure was then projected using the survival ratios from the 1980 national life tables as the point of departure in the initial period of projection and adapting the Coale and Demeny West Model life tables to project the age structure according to the projected levels of expectation of life.

It is interesting to note the incongruity observed in the gap between the male and female infant mortality rates, which increase as the expectation of life at birth rises in the projections. Indeed, it appears that the rate of decline for females is faster than that for males, thereby resulting in an excessive widening of the gap between the sexes.

This finding has also been noted for other countries⁶ and seems to reflect a limitation of the model life tables being used. It has been found to occur especially when the expectation of life of a country is of a high level.

Given the predictable nature of mortality in these countries and the small effect on the age composition, only one hypothesis was assumed for the projections.

D. FERTILITY

An average of the data on births by age of mother for the three years surrounding the 1970 and 1980 censuses as well as the mid-year female population were used to calculate the age-specific fertility rates (ASFR) after which the total fertility rates (TFR) were established.

As illustrated in Table 1.2, despite the wide variations observed, the level of fertility among most of the countries is comparatively low (with the exception of Belize and possibly Saint Lucia). The structure also corresponds closely to that of a young fertility model, with the peak occurring in the younger age group (20-24).

TABLE 1.2
TOTAL FERTILITY RATE (1960 - 1980)

Country	1960	1970	1980
Belize	...	6.3	...
The British Virgin Islands	...	3.6	2.4
Dominica	7.4	...	3.1
Grenada	6.3	4.3	3.4
Montserrat	...	4.1	2.4
Saint Christopher and Nevis	6.8	5.1	3.4
Saint Lucia	6.9	6.1	4.1
Saint Vincent and the Grenadines	7.3	6.1	3.9

The projection of fertility was conducted in two stages. In the first stage, the level of fertility was projected in accordance with the logistic function. Then, secondly, the age structure was projected adopting two approaches for analytical purposes. The first used the United Nations age schedule model while, in the second, the ASFRs were adjusted linearly according to changes in the TFR over time.

⁶Ortega Antonio - "Tablas Limites de Mortalidad Preparadas en CELADE - San Jose para su uso en proyecciones de Población", CELADE, 1984.

The reason for adopting both approaches was based on the fact that, although the use of the model age schedule was considered more appropriate, some small differences were observed in the age structure of the ASFRs for the United Nations model in comparison to that for the Caribbean countries. Essentially, the ASFR for the age groups 15-19 in the United Nations model was lower while that for the ages 20-24 appeared higher.

However, as illustrated, results from the projections indicate minor differences (of less than 3%) between the total populations projected under alternative approaches. On the whole, the total projected populations utilizing the United Nations age schedule were higher than those with projected linear declines in the ASFRs. The differences, which varied between 0.4% to 3.0% depending on the level of fertility of the country, appeared to be largely the result of the higher proportion of females in the 20-24 age group (most fertile period) for the United Nations model.

Fertility Level

Having analyzed the fertility trends over the past three decades, and taking into account the TFR for two or three periods, the future evolution of fertility was estimated based on the theory that the behaviour of fertility decline follows the shape of a logistic curve:

The function adopted is as follows:

$$TFR(t) = K_1 + \frac{K_2}{1+e^{a+bt}}$$

TFR = Total Fertility Rate at time t

K_1+K_2 = The highest asymptote, corresponding to the highest TFR observed for the country in the past

K_1 = The lowest asymptote - the lowest value in the transition process over the projected period (possibly replacement level)

$a + b$ = parameters

The value of a and b are then derived from the following system of equations:

$$a = \ln \left(\frac{K_1 + K_2 - TFR(0)}{TFR(0) - K_1} \right)$$
$$b = \frac{1}{t} \left(\ln \left[\frac{K_1 + K_2 - TFR(t)}{TFR(t) - K_1} \right] - a \right)$$

The main advantage in selecting a logistic curve to depict the fertility evolution is that variations in the TFR are more gradual, thereby reducing the possibilities of irregularities in the projected total number of births and the consequent inconsistencies in the age-sex structure of future populations.

Projection of Fertility Age Structure

After completing the projection of the fertility levels, the age structure of these levels were estimated utilizing two methods. In the first approach, the United Nations theoretical model⁷ of medium fertility with the early peak was selected. Taking the age structure of the model as a limit and the ASFR of the country as the starting point, the ASFRs for the projected periods are interpolated in relation to the projected levels of TFR.

With regard to the second method, the ASFRs are obtained through linear interpolations taking into account only the values of the calculated total fertility rates.

E. MIGRATION

A number of data sources were used to establish the level of migration in the countries. These included:

- (a) Annual statistics (1971-1983) on Caribbean immigrants to United States and Canada, obtained from the United States and Canadian immigration departments;

⁷See United Nations - "Population Bulletin No. 7", New York, 1963.

- (b) Data on net migration from National Statistical Offices; and
- (c) Data from the Eastern Caribbean Migration Project Survey of 1984.

In addition, the residual method technique was utilized to estimate the total number of migrants between 1970 and 1990. In the method, the 1970 and 1980 census data was used to calculate ten-year census survival ratios. The latter were then applied to the 1970 and 1990 censuses to make forward and backward projections.

An average was then made of the differences between the actual and estimated populations for 1970 and 1980 thus yielding an estimate of net migration for the ten-year period. Thus:

$$M_1^{x+t} = P_t^{x+t} - sP^0$$

- Where:
- x = age-group
 - t = census interval
 - P^0 = Population aged x at first census
 - P_t^{x+t} = Population in next census age $x + t$
 - s = survival rate

$$M_2 = \frac{P_t^{x+10}}{s} - P_o^x$$

and average net migration

$$M = \frac{M_1 + M_2}{2}$$

The results of the residual method were found to correspond closely to those from other data sources. Thus an average was used as a basis for projecting total migrants.

With regard to the age-sex composition, an age structure, based on the average of three years of recent data on migrants from the Republic of Trinidad and Tobago and Jamaica obtained from the United States Immigration Office was selected.

F. PROJECTIONS - METHODOLOGY AND ASSUMPTIONS

Methodology

For this population projection exercise, the projection Computer Programme of the United Nations, which relies on the component method, was utilized.

The basic input data comprises the following:

- base population, distributed by age and sex.
- the expectations of life at birth for 5-year periods and the corresponding survival ratios by age and sex.
- the total fertility rates for each 5-year period as well as the related age-specific fertility rates.
- total number of migrants by sex and distribution.
- the value of the sex-ratio at birth.

The general methodology of this programme is as follows: First, the age-sex specific survival ratios are applied to the corresponding age-sex of the base population to estimate the survivors age 5 and over. Then age-specific fertility rates are multiplied by the average numbers of women in the reproductive age-groups, 15 to 49 years, in the projection interval, yielding the sum of the number of births during the five-year period. Next, through the application of the sex-ratio at birth and the survival ratios for births 0-4, the numbers of males and females aged 0-4 at the end of the five-year period are obtained and added to the survivors aged 5 years and over. Finally, the estimates of the net numbers of migrants by age and sex during the projection interval are added to the projected base population, thereby producing the total population by age and sex at the end of the five-year period.

Fertility

In general, four alternative assumptions about the trend of future fertility were made for each country, one of these being Constant:

- (i) Constant Assumption - Total fertility rate remains constant at the 1980 level throughout the projection period;
- (ii) High Assumption - Total fertility rate declines to the replacement level at a late date (between approximately 2000-2005) depending on the initial level and speed of decline of each country;
- (iii) Medium Assumption - Total fertility rate reaches replacement level at an earlier date (between 1990 - 2000), again corresponding to the initial level and speed of decline of the TFR; and
- (iv) Low Assumption - Total fertility rate reaches replacement level very early.

The latter assumptions were formulated after due consideration was given to the socio-economic fertility determinants and development policy thrusts of the governments of each country as well as a review of past demographic trends.

Migration

Four alternative assumptions concerning the net annual number of migrants are used, again one being the Constant:

- (i) Large/Constant - It is assumed that a large flow of net migration would be maintained. Thus migration is kept constant;
- (ii) Medium - Emigration declines linearly to 50% of the net annual out-flow at an early date (1995) and then remains constant;
- (iii) Small - The tapering off of migration is much slower than in the previous assumption, as emigration declines to 50% of its annual out-flow at a later date (2005) after which it remains constant; and
- (iv) In the case of countries experiencing immigration a fourth assumption assumes that out-migration will slowly increase over time, thereby reducing the net inflow ultimately to zero (either at an early or later date)

Mortality

The average life expectancies at birth for each country are assumed to increase moderately in a logistic fashion depending on the initial levels in 1960 and 1970 as well as the shape of the slope. On average, the rate of increase corresponds to approximately 0.5 to 1 year every five-years.

Only one assumption is made, for mortality, given the small effect on the age composition and growth of the population due to the low mortality levels prevailing.

Choice of Projection Scenarios

Given the importance of net migration on the population growth rates of the Caribbean countries, the decision was made to combine the three migration assumptions with each fertility assumption. Thus, a combination of fertility, migration and mortality assumptions yields a total of approximately ten scenarios for each country.

For this study, however, it was necessary to limit the number of scenarios to be published. It was therefore decided to limit them to four (except for Belize-5), one being the Constant in each case. The other three are designated 'High', 'Medium' and 'Low' and are derived by combining the like assumptions of fertility and migration.

PART TWO

ANALYSIS OF THE PROJECTIONS

I. INTRODUCTION

There is, in the Commonwealth Caribbean countries, a growing demand for population projections on the part of government agencies, particularly those involved in general or specific social and economic planning, as well as on the part of an increasing number of business and other non-government agencies. In addition, organizations concerned with population and population policy now require population projections for a clearer understanding of the dynamics of existing demographic levels and trends.

To project the population of a country, it is necessary to make specific assumptions about the probable future trends in the three components of population growth - births, deaths and migration. These assumptions fully determine the projections which should not, therefore, be uncritically used as forecasts of the future population; they are, in fact, merely statements on what the size and composition of the population would be like in the future, if the stipulated assumptions did in fact occur.

Precisely because it is impossible to foretell the myriad of developments that will occur, even in the near future, and how these will affect the balance of births, deaths and migration, it is usual for demographers to prepare not one, but several projections, based on varying assumptions. A demographer or a user agency may then select one of these as the most likely and in this sense use it as a kind of forecast as is done, for example, when education planners use a particular projection to anticipate and seek to provide for the expected school population in some future period.

With such uses in mind, demographers may seek to prepare 'realistic' projections. Often three such projections are prepared, one intended to show the highest and another the lowest likely population at specified future dates, while the third is intermediate and is usually taken as the 'most likely' projection. But this must not make us lose sight of the fact that all we have, nevertheless, is a set of projections which do not tell us what the future population will be, but rather what it could be. Indeed, projections therefore enable policy-makers to see how the country's future population may affect and be affected by their socio-economic and population goals and policies, and thus provide them with an opportunity to take steps to prevent the occurrence of some undesirable projections.

In addition to ‘realistic’ projections, it is also useful to prepare one or more ‘benchmark projections’ which are ‘designed to illustrate the demographic consequences of certain events which are admittedly not expected to happen ...’. One common example of this is a ‘constant variant’ which assumes no change in one or more of the components of growth.

THE ASSUMPTIONS

Mortality

To project mortality trends, a life table was constructed for the base year (1980) for each of the six countries with suitable data and an appropriate life table was adopted for the other two countries. Using this 1980 life table and on the basis of the past trends in mortality in the region, a suitable model and pattern of change were selected from the Coale and Demeny Regional Model Life Tables. There has been an appreciable improvement in mortality in the region since the 1920s, the improvement being very rapid until the last decade or two when it has been slowing. The implied assumption of the models adopted is that over the whole period of the projections, the moderate but steady improvement will continue.

Fertility

Fertility trends are at once much more critical and much more difficult to anticipate than mortality trends: more critical since the number of births in these countries so far exceeds the number of deaths, that a given percentage error in the former would have a much greater influence on the projected total population; more difficult in that fertility levels and recent fertility trends are much more diverse than mortality levels and trends. Moreover, because of the large number of economic, social, cultural and other factors which influence fertility, there is, as yet, little basis in fact or theory for determining probable future fertility trends. The total fertility rate (TFR) at 1980 was derived for each country. The approach adopted in the series of projections is to select, for each country, three dates by which it is assumed that the total fertility rate would fall to replacement level, taken as 2.1 children per woman.

Migration

The demographer, however, faces his greatest difficulty and uncertainty when he seeks to determine the likely future trends in net migration. There are a number of reasons for this. One is that despite the importance of migration for the region, both the quantity and the quality of migration statistics are very poor. Another is the failure of past analysis to give any clear, convincing indication of what the net effect of the many and conflicting determinants is likely to be. It is known that there is a potential for very large-scale emigration because of the high levels of unemployment and the low levels of social and economic development in the Caribbean, as compared with the countries of North America.

On the other hand, however, there are quite severe restrictions on immigration into these countries from the Commonwealth Caribbean. Yet emigration has been quite heavy, much of it being, no doubt, illegal. Among the questions to be determined are: will the 'receiving' countries change their attitudes to and modify their restrictions on immigration from the Commonwealth Caribbean during the projection period, and if so, how? Will the social and economic conditions in the region change enough to affect the propensity to migrate? Will there be greater success in preventing illegal migration?

Many demographers had anticipated a fall in emigration from the region after the high levels of the 1960s. This has not occurred and, instead, emigration has continued to increase. On the other hand, in one of the countries at least - Belize - in recent years there has been a growing immigration, again largely illegal, and there has also been a small net immigration into the British Virgin Islands.

Nevertheless, once again the projections are based, for the most part, on the simple assumption that there will be some reduction in the net number of migrants, the size and the speed of such decline being made to vary within each country for the various variants. The number of migrants rather than the migration rate has been used in view of the crude nature and poor quality of the base data on net migration.

THE VARIANTS

In accordance with usual practice, a number of variants have been prepared for each country. Of these, four have been selected for presentation in this study. One of these is a benchmark projection, which assumes a constant level of fertility and a constant number of migrants over the whole projection period. As indicated earlier, this is unlikely to occur, and is included merely in order to demonstrate what would happen if the present high levels of fertility continue with no change in the number of migrants.

Three 'realistic' variants have been prepared for each country. For all of these, a single set of mortality assumptions has been used in each country as indicated earlier. However, three separate sets of assumptions were made for fertility and for migration (see Part One), the first representing the changes considered most likely to occur in these two components, and the other two representing, respectively, the highest and the lowest contributions that each of these components appears likely to make to population growth.

In the case of fertility, this is straightforward: the assumption with the least or the slowest rate of decline in fertility is the 'high' assumption. In the case of migration, in most countries there has been a net loss of population in recent decades. The assumption which envisages the smallest decline in net emigration is conducive to the highest population growth. For the two countries where there has been net immigration, the 'high' assumption is the one in which immigration increases most rapidly or declines most slowly.

The 'high' fertility and 'high' migration assumptions have been combined for the 'high' variant, and conversely, the 'low' fertility and migration assumptions produce the 'low' variant. The 'medium' (most likely) assumptions are combined to produce the 'medium' variant.

THE ANALYSES

The basic table in this study shows the population at 1980 and the projections of the population (the four variants) at 5-year intervals for the period 1985-2015, by age and sex. (Appendix I for each country). After a brief discussion of the projected population growth, we investigate the contribution which each of the three components - births, deaths and migration - have contributed to this growth. In the analysis, the numbers of population and of births, deaths and net migration are rounded to the nearest 100. In the tables, however, these numbers are given in full, that is, to the nearest unit. Users can, therefore, round the numbers as is appropriate for their individual use.

We next examine the most important demographic impact of population growth - the changing age composition of the population and its policy implications. Each of the components of growth contributes to this. A high fertility rate favours an increase in the younger age groups and, conversely, a lower fertility rate favours a fall in the proportion of young people. On the other hand, a low death rate and/or an improving mortality favours an increase at the higher ages. Emigration, since it tends to include a disproportionately large number of persons of young working age, will contribute to a fall in the proportion of persons in this middle age span. The fertility rate and, to a somewhat lesser extent, the migration level, can be expected to have a more important and direct impact on the age composition of the population in the region than the level of mortality.

The sex distribution is also now of considerable interest. The usual summary measure here is the sex ratio - males per 1000 females. The components of growth also have differential effects on the sex distribution of the population. In general, male births exceed female births by a factor of about 1050:1000. We would expect, therefore, that the sex ratio would be slightly in favour of males at the youngest age groups. This imbalance, however, soon disappears because of the higher mortality among males. Because females tend to live longer than males, there is a tendency for the sex ratio to be in favour of females at the higher age groups.

But the component likely to have the greatest effect on the sex distribution is migration. In the past a preponderance of emigrants were young males. The indications are that this pattern has now changed and that women emigrate more than men. For the projections it is assumed that the sex ratio of emigrants is about 750 males per 1000 females. A high emigration, therefore, is in favour of a high ratio of males to females.

A measure often used to indicate the significance of the age distribution of a population is the 'dependency ratio'. This is not a measure of economic dependency, such as might be attempted by relating the economically inactive to the economically active population, but is simply a ratio of the population above or below working age (taken as 15-64 years) to the population of working age.

The median age is a simple, composite measure of the age distribution of a population. These two indicators of the age distribution are discussed.

We conclude the analysis for each country with a brief discussion of changes implied by the projections in the vital and reproduction rates.

Note on a Minor Internal Inconsistency in the Projections

The projections have been constructed on a microcomputer using a programme provided by ECLAC/CELADE, Santiago, Chile. One numerical inconsistency has been observed. Total growth derived from two sources: (a) the population equation (Birth minus Deaths plus/minus net migrants); and (b) the difference between the opening and closing population, are not identical. For Saint Lucia, for example, for the period 1980-2015, for the medium variant, growth according to (a) is 95,555, and according to (b) 95,401.

II - BELIZE

PROJECTION ASSUMPTIONS

Mortality

The average length of life (expectation of life at birth) was 70.4 years for males and 72.6 for females; females exceeding males by 2.2 years. It is assumed that this will be the level for the first 5-year period 1980-1985, and that it will increase gradually to 73.3 and 76.0 respectively by 2010-2015, the sex differential increasing to 2.7 years.

Low	-9000	-8357	-7714	-7071	-6428	-5784	-5143

Fertility

The total fertility rate (TFR) was 5.9 in 1980, the highest in the region. For the high variant, it is assumed that the TFR in 1980-1985 will be 5.4 and that it will fall to 3.0 in the last quinquennium (2010-2015).

For the medium variant, the assumption is that the TFR will fall from 5.3 in 1980-1985 to 2.1 (replacement level) in 2010-2015, while for the low variant the assumed decline is from 5.2 in 1980-1985 to 2.1 in 2005-2010 and thereafter.

Migration

For the high and medium variants it is assumed that net emigration, which was 9,000 for the 5-year period 1980-1985, will fall to one-half (4,500) by 1995-2000 and 2005-2010 respectively. It is assumed that the low variant will fall by just under 650 per 5-year period to 5,140 in the quinquennium. It is known, however, that there is a large and increasing immigration into Belize from Mexico and, in recent years, from Haiti. There is, moreover, an expressed interest on the part of the Government of Belize, in the use of immigration to assist in the development of the country's large unused hinterland. It has therefore been decided to provide a fourth 'realistic' variant in this case, using the medium assumption on fertility and the assumption that net migration will decline to zero by the year 1995. For convenience this is called the medium/high variant.

ANALYSIS OF RESULTS

The Total Population

The total population of Belize was 145,400 in 1980. If there were no reduction in the fertility level, and no change in the number of migrants (the constant variant), the population in 2015 would be 2¾ times as large - over 401,000. The realistic variants, however, project a much smaller increase to between 243,200 (low) and 311,000 (high). As stated above, two medium or "most likely" variants are provided, differing only in terms of the assumed net migration (see above). The medium variant projects a population of 266,700 by 2015, while the medium high projects 305,700.

Constant Variant						
1980	145353			145353		
1985	163786	2.4	29	161326	2.1	33
1990	187557	2.7	26	181448	2.4	29
1995	216138	2.8	25	204907	2.4	29
2000	249622	2.9	24	231005	2.4	29
2005	289917	3.0	23	257918	2.2	31
2010	339606	3.2	22	284929	2.0	34
2015	400913	3.3	21	311029	1.8	38
Medium Variant						
1980	145353			145353		
1985	160825	2.0	34	160174	1.9	36
1990	178410	2.1	33	176617	2.0	34
1995	197541	2.0	34	193221	1.8	38
2000	217113	1.9	36	208681	1.5	46
2005	236344	1.7	41	221880	1.2	58
2010	253300	1.4	49	231735	0.9	77
2015	266737	1.0	69	243157	1.0	69

The rate of growth in the first quinquennium 1980-1985 was projected to be 1.9 percent per annum for the low variant, 2.0 for the two medium variants, and 2.1 for the high variant.

By the end of the projection period - 2010-2015 - the low and the medium variants will be increasing by 1 percent per annum, the medium/high by 1.4 percent and the high variant by 1.8 percent per annum. For all four realistic variants, the rate of growth will increase at first and then decline, the first period of decline being 2000-2005 for the high and medium/high variants, and ten years earlier - 1990-1995 - for the other two variants.

BELIZE
TABLE 2.2A: TOTAL POPULATION 1980 AND PROJECTIONS 1985-2015 EXPONENTIAL RATES OF GROWTH, AND NUMBER OF YEARS FOR THE POPULATION TO DOUBLE, MEDIUM/HIGH VARIANT

Year	Population	Growth Rate	Years to Double
1980	145353		
1985	160825	2.0	34
1990	180793	2.3	30
1995	205133	2.5	28
2000	233014	2.5	28
2005	260445	2.2	31
2010	284892	1.8	38
2015	305737	1.4	49

The rate of growth at the end of the projection period implies that the population at that time will double itself in 69 years in the case of the low and medium variants, but in as little as 38 years for the high and 49 years for the medium/high variants.

The Components of Population Growth

The total population growth over the 35-year period 1980-2015 ranges from 98,000 (low variant), to 166,000 (high), the growth of the medium and medium/high variants being 122,000 and 160,000 respectively.

The difference between the high, the two medium and the low variants in total growth, is primarily due to the difference between the number of births, which ranges from 182,000 (low) to 244,000 (high), the number for the medium and medium/high variants being 202,000 and 216,000 respectively.

On the other hand, the number of deaths is not very different for the various variants, being 35,000 for the low and 38,000 for the high variants. The contribution of net migration is also limited if we exclude the medium/high variant, the number of emigrants (net) being 40,500, 45,000 and 49,500 for the high, medium and low variants respectively.

Total	202451	35712	-45000	121739	182372	34683	-49497	98192
Low Variant								

It is in this regard that the medium/high variant is different from the others, in that the assumed migration for the 35-year period is only 18,000, it being assumed that net migration will be zero from the year 2000 onwards. Since the fertility and mortality assumptions of the two medium variants are identical, it is this difference in migration that accounts for the whole difference of 39,000 in the population growth to 2015 between these two variants.

The average annual number of births will increase in each successive 5-year period in the case of the high variant from 5,900 per year in 1980-1985 to 7,500 in 2010-2015. In the other three variants, the number of births per year is projected to increase at first and then decline. Births will reach their peak in 1990 for the low variant and in 1995 and 2000 for the medium and medium/highvariants respectively. In each of these variants, the average annual number of births at the end of the projection period will be lower than at the beginning.

Despite the improving mortality situation, the quinquennial number of deaths is projected to rise slowly, from 4,500 in 1980-1985 to between 5,700 (low) and 6,400 (high).

Age Distribution

In 1980 slightly less than one-half of the population was of working age, 21 percent of the population being in the young adult group (5-14 years) and 28 percent in the mature working age group (25-64 years). The population of school age (5-14 years) was 29 percent, marginally larger than the mature working age group, while the pre-school population (0-4 years) comprised 17 percent of the total. Five percent of the population was 65 years and older.

The population of mature working age is the only one that is projected to increase as a proportion of the total over the projection period. From 28 percent in 1980 and 1985, this group is projected to be nearly one-half of the population for the low variant, and slightly less (47 percent) for the medium variants. It will be much lower (41 percent) according to the high variant.

The other two adult groups - the young adults and the old-age dependents - are projected to change only very marginally, the former falling from 21 to 20 percent and the latter from 5 to 4 percent.

The pre-school and school-age populations, on the other hand, are both projected to fall appreciably, the former from 17 to 9 percent for the medium and low variants and 12 percent for the high, and the latter from 29 to between 17 and 23 percent. For both groups the decline is more rapid towards the end of the projection period.

The age distributions for the medium/high variant (Table 2.4A) are the same as for the medium throughout the projection period, except for the 25-64 and 65+ age groups where there are very minor differences.

Table 2.5 shows that for the medium variant, the pre-school age group, after increasing to 22 percent higher than in 1980 for the years 1995 and 2000 will fall to 6 percent below the 1980 figure in 2015. The school population is also projected to rise at first, but after 2005 it will fall though remaining 24 percent higher at the end of the period than in 1980. The three age groups covering the population 15 years and older are all projected to increase steadily over the period, the young adults and the old-age dependents being 79 and 76 percent higher than 1980, respectively, while the population of mature working age will be more than 3 times as large as in 1980.

Low Variant												

*Due to rounding figures may not add to 100

In the case of the low variant, both the pre-school and the school-age populations will be smaller at the end than at the beginning of the projection period, the index numbers being 88 and 98 respectively. In both cases, the population will increase at first, the pre-school

index reaching 115 in 1990, and the school-age index 124 in 2000. The age groups 25-64 and 65 and over will both increase steadily over the period, while the young adult group is projected to increase up to 2010 and will then fall slightly. Once again the population of mature working age is projected to increase considerably more than the other groups, the index for this group being 292 in 2015, as compared with 158 and 173 for the younger and older groups respectively.

According to the high variant, the population will increase steadily for all age groups. By 2015 the young adult population will be more than twice and the population of mature working age will be more than 3 times as large as in 1980. The pre-school group will grow least, the index number in 2015 being 148, while for the other two age groups the index reaches 164 for the school-age population and 182 for the dependent old-age population.

A more detailed age breakdown, by 5-year age groups, is shown in Diagram 1. The age pyramid for 1980 is typically bell-shaped, the age groups decreasing in size as age increases, fairly quickly and uniformly up to age 35-39, and then continuing to decrease at higher ages but much more slowly. Unlike most of the other countries of the region, there is no evidence of a recent fall in the birth rate as the age-group 0-4 years is the largest of the 5-year age groups.

By the year 2015, the pyramids for all of the realistic variants will have a quite different shape, being much narrower than at 1980 for the age groups under 20 years old. In addition, the 2015 pyramids are all convex in shape while the 1980 pyramid was concave.

The pyramid for the high variant is the only one which in the year 2015 has a pyramid that gradually reduces in width as age increases over the whole age span. For the medium/high, medium and low variants, the age group with the largest population is 10-14, 15-19 and 20-24 respectively, the pyramids narrowing at higher and lower ages.

Dependency Ratios

In 1980, the dependent young and old populations together exceeded the population of working age, the dependency ratio being 1032 . For all four realistic variants, however, it is projected to fall continuously over the projection period. By the year 2015, the ratio for the high variant is projected to fall to 612; for the other variants it will be very much lower, being 444 for the low and over 491 for the two medium variants. The declining dependency ratio is, of course, the result of the more rapid increase in the population of working age than in the dependent young and old populations.

Low Variant						

Aging of the Population

Given the high fertility rate, the population of Belize was very young; in 1980, the median age of the population being 16.6 years. With the assumed decline in the fertility, the median age is projected to rise in all of the realistic variants. According to the low variant, in which the fertility rate falls most rapidly, the median age will be 27.2 years by 2015; on the other hand, the age will be just 22.8 years according to the high variant. For the two medium variants a median age of 25½ years is projected.

Sex Distribution

In 1980, there were 1026 males per 1000 females in the population. According to the medium/high variant, the sex ratio will grow to 1048 by 1990, but then fall steadily to be almost the same at the end as it was at the beginning of the projection period. For the other three realistic variants the sex ratio will continue to increase for most of the projection period and will be between 1051 and 1071 in the year 2015.

Sex ratios by age (5-year age groups) are given in Appendix II. For the two medium variants for 1980, there were more males than females at every age group under 65 years, the sex ratio being particularly high at age 40-44 (1096) and 50-54 (1107).

In 1980, the sex ratio at age 0-4 was 1016; on the basis of the assumed sex ratio at birth of 1030, it is projected that the ratio for the 0-4 age group will be 1020 in 1985 and will gradually increase to 1024 by 2015.

According to the medium variant, with few exceptions, the sex ratio for each-cohort will increase to age 65-69 (or the highest age reached for younger cohorts) and then decline. The exceptions are the three age groups covering the age span 20-34 years in 1980, for which the increase continued only up to age 55-59, the two cohorts aged 75-79 in 1985 and 1990 for both of which there was a small increase in the sex ratio at age 80 and over.

As an example, the cohort aged 35-39 in 1980 had a sex ratio in that year of 1034, which is projected to increase continuously to 1143 in 2010 at age 65-69. The cohort aged 0-4 in 1980 will experience an increase in its sex ratio from 1016 in 1980 to 1084 in 2015 at age 35-39.

This increase in the sex ratios can only come about because the excess of female over male emigrants will be much greater than the excess of male over female deaths according to the assumptions. For this reason, in the case of the medium/high variant in which it is assumed that emigration will cease by 1995, the sex ratios for later years are very much lower than for the medium variant.

For example, the sex ratio at age 50-54 in 2015 is projected to be only 1042 according to the medium/high variant as against 1104 for the medium. Moreover, for the medium/high variant after 1995 the sex ratios begin to decline much earlier (after age 50-54) than for the medium variant (after age 65-69).

The projected increase in the sex ratios - that is, the growing excess of males over females - accompanied by, and indeed largely resulting from an assumed greater emigration of females could well lead to some reduction in the effective pressure for dealing with special problems and issues relating to women in the society. Special steps may need to be taken to ensure that these problems and issues continue to be highlighted and that real progress is made in improving the status and welfare of women throughout the projection period.

BELIZE
TABLE 2.6A: DEPENDENCY RATIOS, SEX RATIOS AND MEDIAN AGE

Year	Dependency Ratio(per1000)	Sex Ratio (/100females)	Median Age (Years)
1980	1031.5	102.6	16.59
1985	972.5	104.2	17.24

2005	685.8	103.7	21.35
2010	586.6	103.3	23.24
2015	495.9	102.9	25.46

Vital Rates

The crude birth rate (CBR) averaged 37-39 per thousand in 1980 for the realistic variants. The rate will decline steadily throughout the projection period for all of these variants except for a very slight increase for the low variant in the last quinquennium. By 2015, the CBR will be 24 for the high variant and just over 18 for the other three. For the last quinquennium, only the CBR for the low variant will be marginally higher than that for the medium because of a higher proportion of women of child-bearing age.

2010-2015	13.82	18.34	4.52	13.98	18.76	4.78
Low Variant						

The crude death rate (CDR) was just under 6 per thousand in 1980-1985 and is projected to fall slightly to 4-5 per thousand by the end of the projection period.

The net result of these changes is that the rate of natural increase will fall from 32 per thousand in 1980-1985 to 20 for the high variant and 14 for the other three variants.

BELIZE
TABLE 2.7A: VITAL RATES (PER 1000)
MEDIUM/HIGH VARIANT

Five Year Period	Natural Increase Rate	Crude Birth Rate	Crude Death Rate
1980-1985	32.07	37.96	5.89
1985-1990	30.46	35.96	5.49

2000-2005	22.24	26.79	4.55
2005-2010	17.93	22.39	4.46
2010-2015	14.12	18.56	4.45

Infant Mortality Rates

The infant mortality rate, which is the same for all variants, will fall steadily from 39 (deaths to infants under 1 year of age per 1000 live births) in 1980-1985 to 21 in 2010-2015. The male rate will remain much higher than the female throughout, the relative difference increasing over time. In 1980-1985 the IMR for males was 44 and the female rate 33, the male rate being one-third higher than the female. By the last quinquennium, the male rate is projected to be 24 and the female rate 13, the male rate by then being one-half again as high as the female.

BELIZE
TABLE 2.8: INFANT MORTALITY RATES
(PER 1000 BIRTHS)

Five Year Period	Males	Females	Total
1980-1985	43.89	33.49	38.77
1985-1990	38.62	29.77	34.26
1990-1995	34.74	26.52	30.69

2005-2010	26.28	19.66	23.02
2010-2015	24.30	18.17	21.28

Reproduction Rates

In the first quinquennium, 1980-1985, the gross reproduction rate (GRR), is taken as 2.5-2.7. The GRR equivalent to a TFR of 2.1 is 1.04, and this is achieved, according to the fertility assumptions, by 2005-2010 for the low, and 2010-2015 for the medium variants. The high variant is not assumed to reach this level during the projection period; instead, the GRR in 2010-2015 according to this variant will be 1.48.

The net reproduction rate (NRR), which takes into account mortality among women up to the end of the child-bearing period, will be less than 1 for the medium and low variants, at the time that the TFR falls to replacement level. According to the high variant, however, the NRR at the end of the projection period will still be 1.42.

III - BRITISH VIRGIN ISLANDS

PROJECTION ASSUMPTIONS

Mortality

In the absence of adequate mortality data, the mortality schedule and life table for the Bahamas have been used for the B.V.I. projections.

The average length of life (expectation of life at birth) at the outset of the projections was 65.4 for males and 73.3 for females, and it is assumed that by the end of the projection period it would have increased by about 4 years for males and 6 years for females to 69.5 and 77.4 years respectively, with females exceeding males by 8 years.

Medium	125	100	75	50	25	0	0
Low	125	83	41	0	0	0	0

Fertility

The total fertility rate (TFR) was 2.4 in 1980 and it is assumed that it will remain at this level for the first 5-year period 1980-1985 for all variants. Thereafter, it is assumed that the TFR will fall to replacement level (2.1) by 2010-2015, 2000-2005 and 1990-1995 respectively for the high, medium and low variants.

Migration

There is a small immigration, estimated at 20 net immigrants per year, at the start of the projection period, and it is assumed that this will fall to zero by 1995 for the low variant, by 2005 for the medium and by 2010 for the high variant.

ANALYSIS OF RESULTS

The Total Population

Since the levels of fertility and migration were already quite low at the outset, the assumptions for the three realistic variants do not vary much one from the other. As a result, the projected populations are not very different, ranging from 16,500 to 17,200 by the end of the projection period, a difference of only 4 percent between the high and the low variants. We therefore confine our discussion for the most part to only one of these -the medium variant.

With a starting population of 11,000 in 1980, the population is projected to increase, by the year 2015, to 16,900 for the medium variant, as compared with 18,400 on the assumption of constant fertility and immigration.

According to the realistic projections, the annual exponential rate of growth will fall from 1.6 percent in the first quinquennium to 0.8-0.9 percent for the last - 2010-2015. For the constant variant, the rate of growth will fall in the period after 2000 to 1.2 percent at the end of the projection period. According to the medium variant, the population would take 43 years to double itself at the rate existing at the outset, but would take 86 years to achieve this according to the rate of growth in the last quinquennium. Even if there were no decline in fertility and immigration, the number of years to double would still rise from 43 to 58 years (the constant variant).

The Components of Population Growth

The total number of births per 5-year period is projected to increase according to the medium variant, by about 10 percent between the first and last periods, from about 1,200 (240 per year) to 1,300 (260 per year). Since the TFR will decline according to the assumptions, this increase in the number of births will be the result of an increasing number of women of child-bearing age. According to the medium variant, the number of women aged 15-49 years is projected to increase from 2,700 in 1980 to 4,400 in 2015. If there were no decline in the TFR, (the constant variant) the number of births in the 5-year period 2010-2015 would be about one-fifth higher than the figures above, rising from 1,210 in 1980-1985 to 1,590.

The total number of deaths per 5-year period is projected to increase steadily by nearly 50 percent from just under 420 in 1980-1985 to 620 in 2010-2015. Once again the increase in numbers will be the result of the rising population in spite of a declining rate.

According to the migration assumptions, the number of immigrants will fall for the medium variant, by 20 per 5-year period from 100 in 1980-1985 to 0 in 2005-2010 and 2010-2015.

The net result of the above changes in the components of growth is a projected increase in the quinquennial growth of the population from 910 in 1980-1985 to 930 in 1990-1995 and then a steady fall to 680 for 2010-2015 in the case of the medium variant. For the constant variant, there is a steady increase from 910 to 1,080 over the projection period. For the 35-year period as a whole, the projected growth according to the medium variant is 5,890, a net result of 8,990 births, 3,480 deaths and 375 immigrants (Table 3.3).

Age Distribution

The population of mature working age - 25-64 years - is projected to increase significantly as a proportion of the total, from 41 percent in 1980 to 51-53 percent by the end of the projection period. This sub-population will increase steadily until the year 2005 and thereafter will change only minimally. The old-age dependent group - 65 years and over - on the other hand, is projected to remain constant at 6 percent of the total until 2005, and then increase to 9 percent by the end of the projection period.

*Due to rounding figures may not add to 100

The three age groups covering the population under 25 years of age are all projected to decline as a proportion of the total, from 12 to 8 percent in the case of the pre-school population (0-4 years old), from 22 to 15 percent for the school-age population (5-14 years), and from 19 to 15 percent for the young adult population (15-24 years). With the minor exception of the year 1985 for the young adult age group, the proportion either remains unchanged or declines in each succeeding 5-year period for the three age groups.

In the year 2015, therefore, the population of mature working age will comprise more than one-half (53 percent) of the total, the school-age and young adult populations will be 15 percent each, and the youngest and oldest age groups will comprise 8-9 percent each.

2005-2010	99	106	123	190	182	188	181	118	176	150
2010-2015	100	105	125	196	238	194	236	120	180	196

Table 3.5 shows that the population of mature working age will nearly double over the 35-year projection period, the index number for the year 2015 (1980 = 100) being 194-197 for the realistic variants.

The old-age dependent population is projected to increase by nearly 50 percent in the 5-year period to 2005, and then much more rapidly in the last 10 years, the index number in the year 2015 being 238 as compared with 148 in 2005. Because of this rapid growth at the end of the period, the old-age population will have increased more, over the whole 35-year projection period, than the population of mature working age.

The population of the three age groups covering the population under 25 years of age are all projected to fluctuate, but by the end of the period, according to the medium variant, the pre-school population will be the same size as in 1980, while the school and young adult population will be 5 and 25 percent larger respectively than in 1980.

The breakdown by 5-year age groups is indicated in the age pyramids in Diagram 2. In 1980 there is a gradual narrowing of the pyramid for young persons under 25 years of age, implying a slightly increasing fertility rate over that period. The age group 25-29, however, is much larger than the preceding 5-year age group, probably a combination of a higher fertility level and immigration of adults. For older age groups there is, once again, a gradual narrowing of the pyramid.

By the year 2015 the age groups are roughly all the same size up to age 35 because there is little assumed change in the fertility level over the next 35 years, while net migration is negligible.

At age 35-39 and 40-44 there is an increase in the cohort sizes, implying that the fertility level assumed for 1980-1985 is somewhat less than it was for the preceding decade. At higher ages there is a gradual narrowing of the pyramid. For the constant variant the pyramid is more regular in shape, the cohorts remaining at roughly the same size up to age 45 and then reducing in size at higher ages.

BRITISH VIRGIN ISLANDS
DIAGRAM 2 : AGE PYRAMIDS 1980-2015

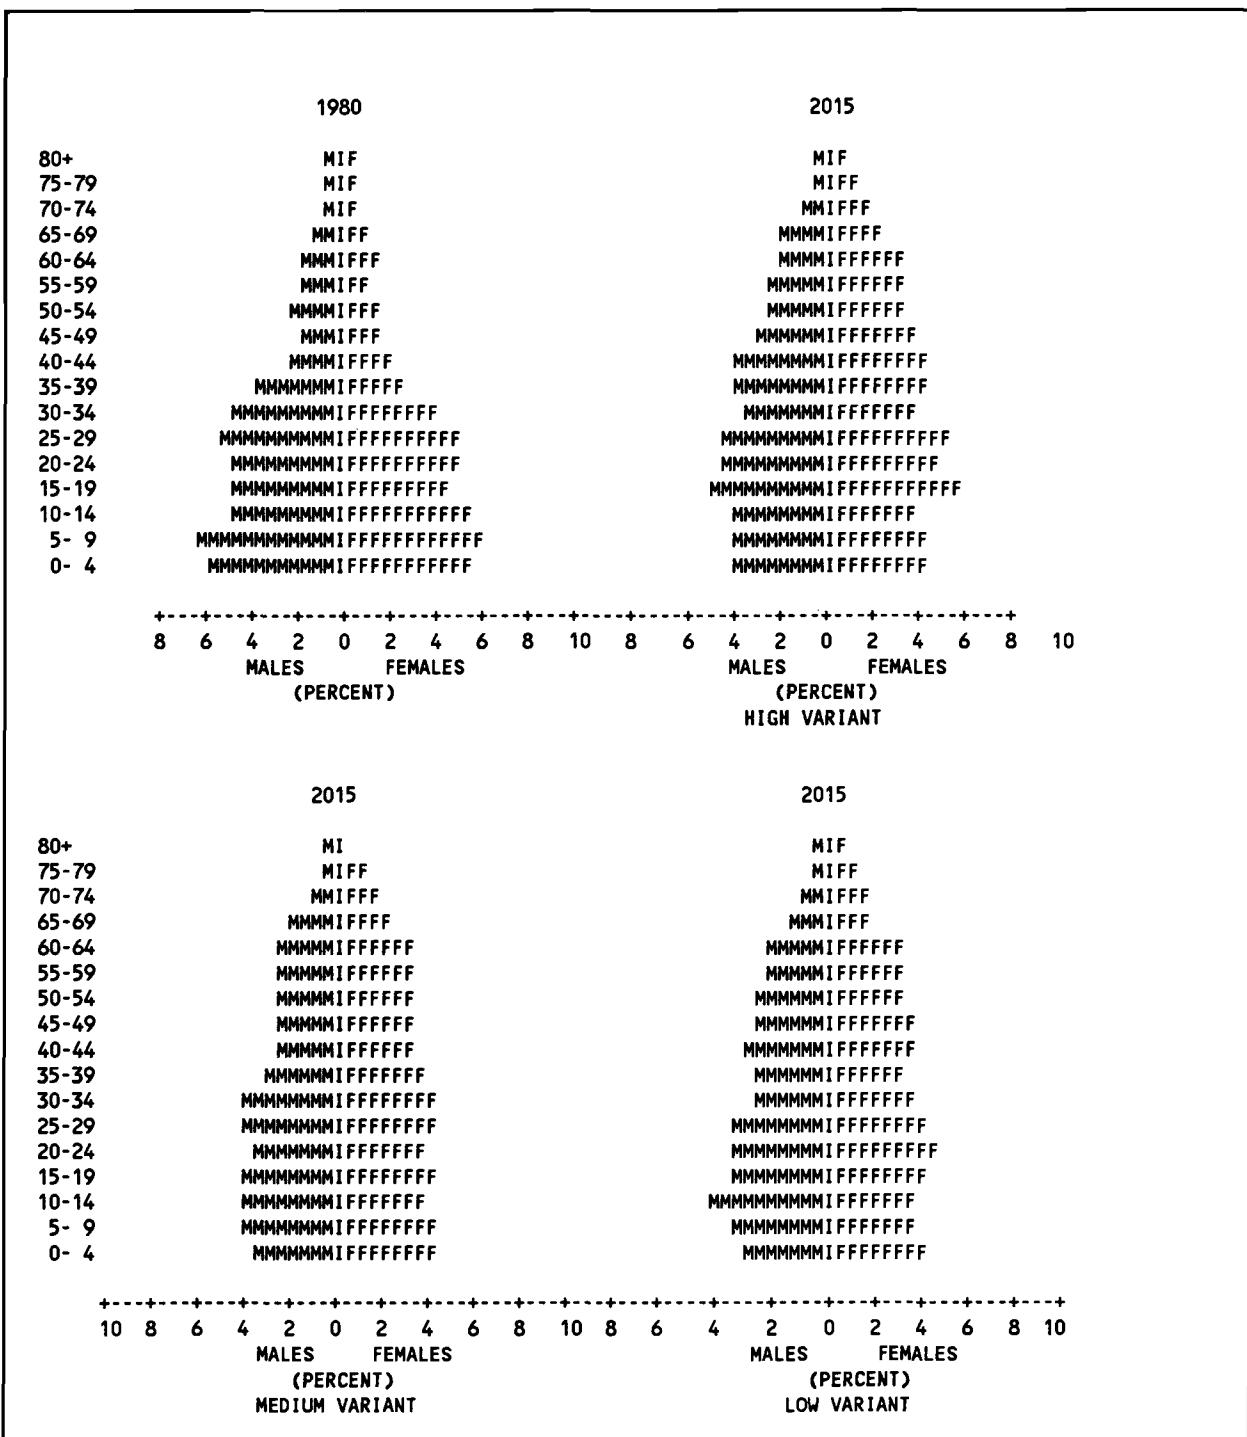

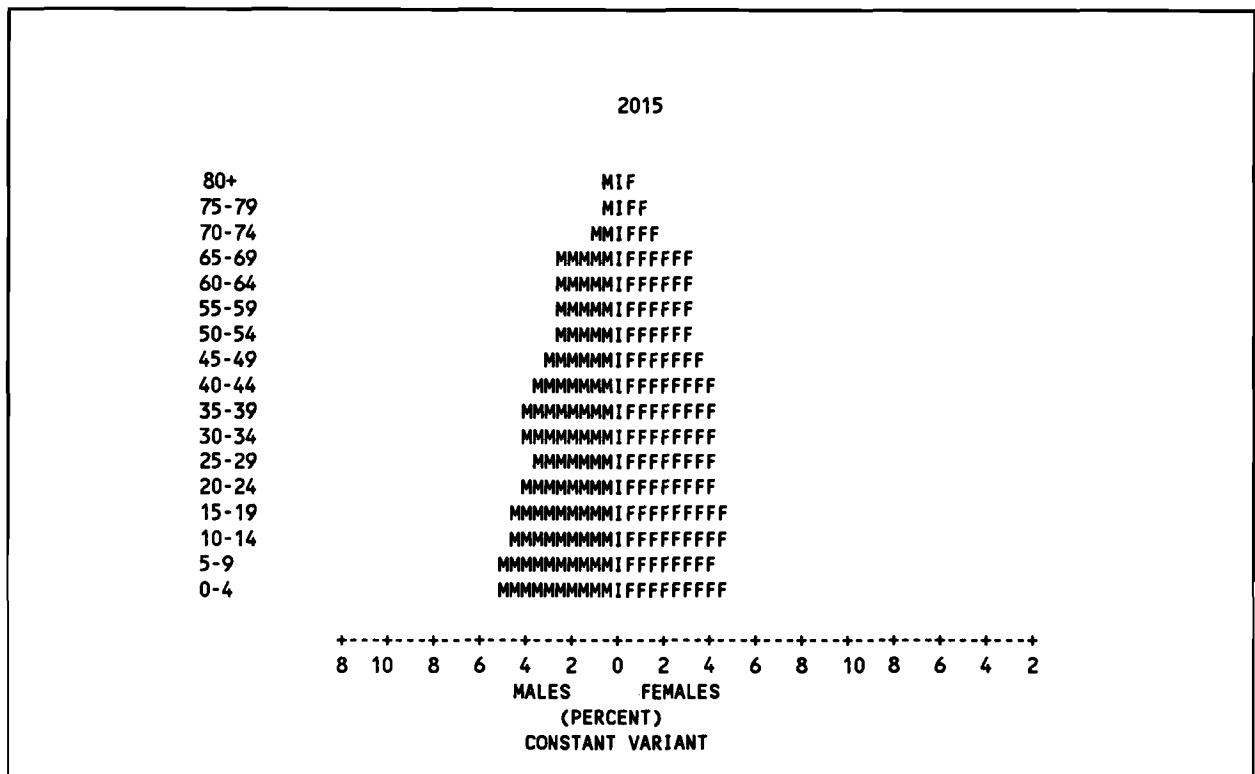

DIAGRAM 2 CONTINUED

Dependency Ratios

The dependency ratio is determined by the proportion of the total population which is of working age. As can be seen from Table 3.4 for the medium variant, this proportion will increase up to the year 2000, but will change only very marginally for the remainder of the period. This is reflected in the dependency ratios which will fall from 667 in 1980 to 477 in 2000 (medium variant), and then to 453 in 2010 before increasing slightly to 469 in 2015. By the year 2015, the dependency ratio is projected to be 476 for the high and 472 for the low variants, indicating little difference since, as we said earlier, the age distributions of the realistic variants are very similar.

BRITISH VIRGIN ISLANDS

2015	469.2	96.5	33.23	472.3	96.4	33.73	33.73	33.73

Aging of the Population

The increasing average length of life will contribute to an aging of the population. In the case of the constant variant, the median age of the population is projected to increase from 23.5 years in 1980 to 31.2 years in 2015. For the medium variant, where the aging is accelerated by the decline in TFR, the median age in 2015 is projected to be 33.2 years.

Sex Distribution

In 1980 there were more men than women in the population, the sex ratio - the number of males per 1000 females - being 1046 in that year. The projections indicate, however, a fall in the sex ratio over the projection period. According to the medium variant, the last year in which males will exceed females is 1995 when there will be just 1002 males per 1000 females. By the year 2015 there will be only 965 males per 1000 females.

The projections assume a surplus of male births (1050 male per 1000 female births). The small emigration is assumed to consist of an equal number of males and females. The projected decline in the sex ratio must, therefore, be the result of the much higher assumed death rate among males.

The sex ratios by 5-year age-groups are given in Appendix II. For the reasons already explained, we will expect each cohort to start with an excess of males in the youngest age group (0-4 years) but the sex ratio to fall steadily over the life cycle.

Thus, the cohort aged 0-4 years in 1980 starts with a sex ratio of 1059 in that year. By the year 2015, when the cohort will be 35-39 years of age, the sex ratio is projected to fall to 1023. And as would be expected, in 2015 the sex ratio for all age groups under 35 years will be over 1000, the ratios falling from 1041 for the 0-4 age group to 1016 for the 30-34 age group.

In 1980, males exceed females for every 5-year age group except the 10-14, 20-24, 45-49 and 60-64 age groups. Over the period, however, females exceed males at an increasing number of older age groups. By 2005 all age groups 30 years and over, except two, will have an excess of females. In 2010 and 2015 males exceed females up to age 34 and 39 respectively, while females exceed males at higher ages.

The special needs of women will, therefore, have to be given increasing attention in the future, particularly the needs of women beyond the reproductive age (45 years and older).

Vital Rates

The implied birth and death rates follow a simple pattern. For the realistic variants, the crude birth rate (CBR) will decline steadily from 21 to 16 per thousand. Even the constant variant projects a fall in the CBR from 21 to 18.

For all variants, the crude death rate (CDR) will fall slightly at first, but from 1995 onwards, despite the falling age-specific death rates, the growing proportion of older persons will result in a slow rise in the CDR to somewhat higher than it was at the beginning of the projection period.

Low Variant						

Infant Mortality Rates

The infant mortality rates show very significant declines. For both sexes together, the rate will fall steadily from 24 to 14 over the projection period, while the female rate, already appreciably lower than the male in 1980, will fall more rapidly and by the year 2015 will be less than one-half of the male rate.

2010-2015	19.61	8.16	14.03

Reproduction Rates

For the medium variant, the gross reproduction rate (GRR) will fall to 1.02 for 2000-2005, this being the GRR related to the assumed TFR replacement level of 2.1. When allowance is made for mortality, this will yield a net reproduction rate of about 1.01 or very slightly higher than replacement (1.0).

IV - DOMINICA

PROJECTION ASSUMPTIONS

Mortality

In the absence of adequate mortality data, the mortality schedule and life table for Saint Christopher and Nevis have been used for the Dominica projections.

The average length of life (expectation of life at birth) at the outset (1980-1985) is 62.8 years for males and 67.9 for females. This gives a male/female differential of 5 years. It is assumed that there will be a steady improvement to 66.4 and 75.4 years respectively for males and females by the year 2015, an increase of just over 3.4 years for males and 7.5 years for females, but this still leaves the average length of life for males in 2015 less than it was for females at the beginning of the projection period, and the sex differential even larger - 9 years.

Low	-3500	-3208	-2916	-2624	-2332	-2040	-1750

Fertility

The total fertility rate (TFR) was 3.1 in 1980. It is assumed that the TFR will fall from 3.0 in 1980-1985 to 2.1 in 2010-2015 in the case of the high variant, from 2.9 to 2.1 in 2005-2010 for the medium variant, and from 2.8 to 2.1 in 1995-2000 for the low variant. In each case, it is assumed that when the TFR reaches 2.1, which is taken as the replacement level, it will remain constant thereafter.

Migration

There was a net emigration of about 700 persons a year from Dominica in the years preceding 1980. It is assumed that this will fall to one-half in each variant: by the year 1995 for the high, 2005 for the medium and 2010 for the low variant. In each case it is assumed that the number of migrants will remain constant thereafter.

ANALYSIS OF RESULTS

The Total Population

The projected rate of population growth for Dominica to the year 2015 is moderate. For the 35-year period 1980-2015, the rate of growth, even for the constant variant, is only slightly higher than 1 percent, and for the high variant is slightly under 1 percent, while according to the low variant, a rate of growth of only 0.5 percent is projected.

With a starting population of 73,900 in 1980, if the level of fertility and the number of emigrants were to remain constant, by 2015 the population will have grown to 107,000. The 2015 population according to the high variant is not much lower than this - 101,500, while for the medium and low variants it is projected as 96,300 and 88,200 respectively.

The projected quinquennial rates of growth increase up to the year 1995 and then decline for all four variants. In the case of the medium variant, the rate of growth increases from 0.6 percent for 1980-1985 to 1.0 in 1990-1995 and then declines again to 0.6 percent for the last two 5-year periods. The highest quinquennial rates of growth achieved for the other variants are 1.3 for the constant, 1.2 for the high and 0.6 for the low.

Table 4.2 also shows the number of years that the population would take to double itself at each of the quinquennial rates of growth. For the interval 1990-1995 - the interval with the highest rate of growth - the number of years is 53 for the constant and 56 for the high variant. On the other hand, for the low variant, even at the highest rate of growth envisaged, the population would take 115 years to double itself, and this period will increase to 173 years by the end of the projection period. For the medium variant, the number of years ranges from 69 for 1990-1995 to 115 at the beginning and at the end of the projection period.

The Components of Population Growth

According to the constant and high variants, the number of births will increase at first until the interval 1990-1995 and then decline; in the case of the constant variant there will be an increase again in the last 5-year interval. The medium variant has a pattern similar to that of the constant, except that the modal interval is 5 years earlier - 1985-1990.

For these three variants, the number of births is appreciably higher for the three 5-year periods covering 1985-2000, than for the rest of the projection period. On the other hand, for the low variant, it is projected that the number of births will fall steadily.

For all variants, the number of deaths is projected to fall in each quinquennium until 2000-2005; and thereafter, with the higher population, the number of deaths will rise again. Here too, however, the number of occurrences at the end of the projection period will be less than at the beginning. But the number of deaths will vary much less than the number of births in both absolute and relative terms. In the case of the medium variant, the projected number of deaths ranges from 610 to 690 per year (averages).

DOMINICA
TABLE 4.3 : COMPONENTS OF GROWTH, 1980-2015

Total	62679	22636	-17500	22543	55074	22229	-18370	14475

Table 4.3 also shows the assumed number of emigrants in each quinquennium, the number declining from 3,500 to 1,750 per 5-year period for the realistic variants.

Of particular interest is the contribution of each of the three components to the total growth over the 35-year period of the projections.

For all variants, the number of births will be by far the largest component numerically, being 3½ times as large as the number of deaths in the case of the constant variant, and 2½-3 times as large for the realistic variants.

But emigration also makes a very significant contribution to population growth (in this case a negative contribution like deaths). If the number of emigrants per year were to remain constant over the projection period, the total number of emigrants would exceed the number of deaths (the constant variant) and even for the high variant, which has the highest number of deaths and the lowest number of migrants, the number of migrants will still be more than two-thirds the number of deaths.

According to the medium variant, the total number of births in the period 1980-2015 will be about 62,700 and the number of deaths 22,600, giving a natural increase of 40,100. However, this may be reduced by emigration to 22,500 or less than 60 percent of natural increase.

The number of deaths is not much different for the various variants, and the differences in projected growth are due entirely to differences in the numbers of births and emigrants. For the high variant, for example, the number of births is projected to be 3,800 more and the number of emigrants 1,700 less than for the medium variant and hence the total growth is about 5,200 more.

Age Distribution

Table 4.4 gives a percentage distribution of the total population. In 1980, the school-age (5-14 years) and the mature adult (25-64) populations were roughly equal in size, with 29 and 31 percent of the total respectively. Somewhat smaller was the young adult group (15-24 years) with 22 percent, while pre-school and old-age dependent groups contained 11 and 7 percent respectively.

The significant change over the projection period, for all variants, is the projected very large decline in the school age and the young adult populations, balanced by an increase in the population of mature working age.

But a closer examination of Table 4.4 shows that the changes in age-structure are projected to be much more rapid at the beginning than at the end of the projected period. Looking first at the population of school age (5-14 years), the proportion in this group is projected to fall rapidly in the first 10 years by 9 percentage points from 29 percent in 1980 to 20 percent in 1990. This is because the age cohorts 5-9 and 10-14 in 1980 are much larger than the 0-4 age cohort in 1980 and (projected) in the succeeding years. In the remaining 25 years of the projection period the proportion increases slightly at first (except for the low variant) and then falls slightly to 15-16 percent for all realistic variants.

In the case of the young adult population (15-24 years), the proportion will increase in the first 5-year period from 22 to 26 percent and, except for the low variant, will then fall only very slightly to 24 percent by 1990. This is again the result of the 5-9 and 10-14 cohorts in 1980 being comparatively large. The proportion will then fall much more rapidly to 16 percent by the year 2000 and will change only very slightly thereafter.

On the other hand, the population of mature working age (25-64 years) is the only group which will constantly increase as a proportion of the total population, from 31 percent in 1980 to 53-57 percent in 2015. The youngest (pre-school) and the oldest (old-age dependent) age groups, which are the two smallest groups in the table, are both projected to fall slightly as a proportion of the total population.

DOMINICA

2015	11	19	18	48	4	100	8	16	18	53	5	100
Medium Variant							Low Variant					
1980	11	29	22	31	7	100	11	29	22	31	7	100
1985	11	23	26	33	7	100	11	23	26	33	7	100
1990	12	19	24	39	6	100	11	19	26	37	7	100
1995	12	20	19	43	6	100	10	19	20	45	6	100
2000	10	21	16	48	5	100	9	18	16	51	6	100
2005	9	20	17	49	5	100	8	17	16	54	5	100
2010	8	17	18	52	5	100	8	16	16	55	5	100
2015	8	15	17	55	5	100	7	15	15	57	6	100

*Due to rounding figures may not add to 100

By the end of the projection period then, the age distribution will be quite different from the outset, with more than one-half of the population in the mature working-age group, 15-17 percent in the school and young adult groups, and 8 and 5 percent respectively in the very young and very old groups.

Table 4.5 shows the population growth of each of the five age groups in the form of index numbers. For each of the variants, it is only the population of mature working age that is projected to grow steadily over the whole projection period; by 2015 the index will be between 221 for the low, and 239 for the high variants. In none of the other age groups is change consistent over the 25-year period.

2010-2015	92	69	101	232	95	79	61	83	221	95
High Variant										
Low Variant										

For all three realistic variants, the population of school age will be well below the 1980 figure in all the projected years, the population falling to 1990, then increasing to the year 2000 and then falling to 69 percent of the 1980 population for the medium variant, and to 61 and 77 percent respectively for the low and high variants.

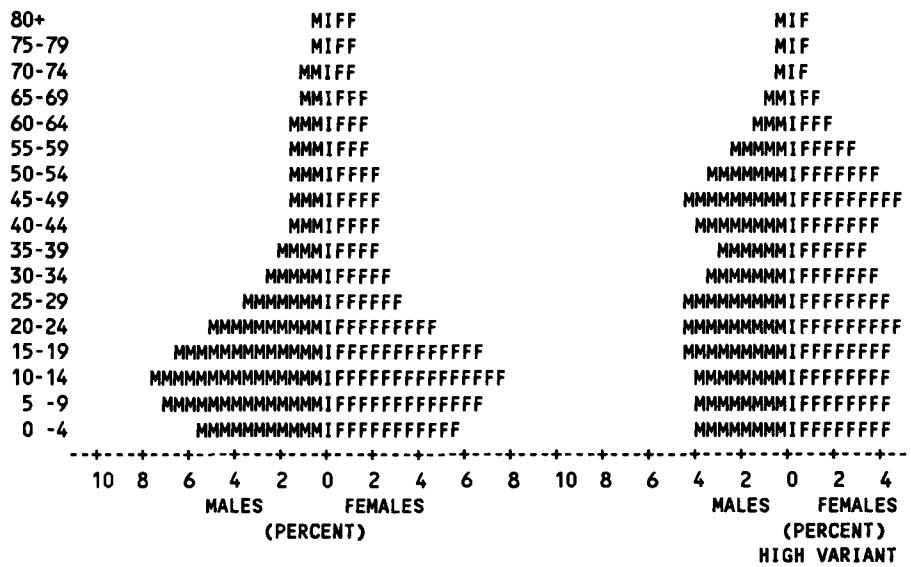

The pre-school age population is projected to rise at first, for the first 10 to 15 years and then decline. According to the high variant, this age group will be slightly larger in 2015 than in 1980, but for the low variant it is expected to be only 80 percent of the 1980 figure.

The old-age dependent population is projected to fall steadily to 2005 when it will be about 87-89 percent of its 1980 size, and then increase by about 7 percentage points in the last quinquennium.

The young adult population is quite irregular as regards its projected growth. For the medium and low variants it is projected to increase by 19 percent by 1985 and then fall to 85-82 percent in 2000. According to the medium variant it will then increase again, while the low variant shows no appreciable change thereafter. For the high variant, after the initial increase to 118 in 1985, there will be little change to 1995; but then there will be a steep fall to 88 in 2000, followed by an increase again.

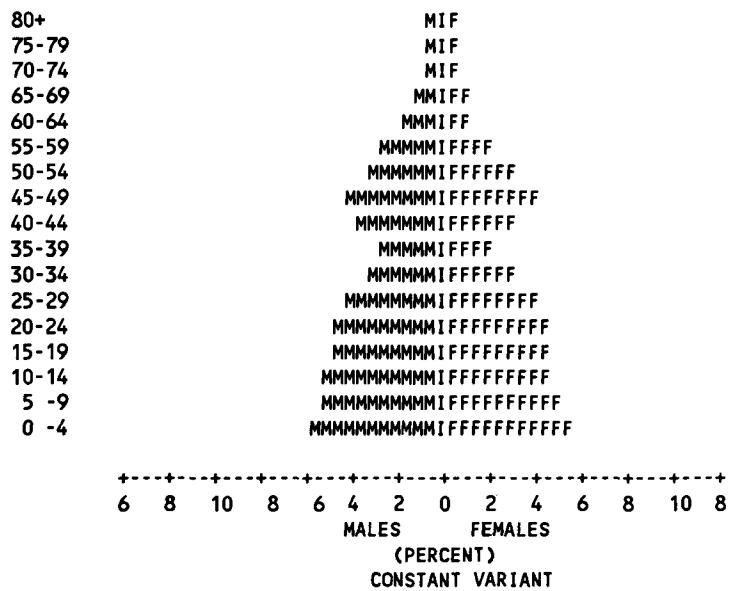

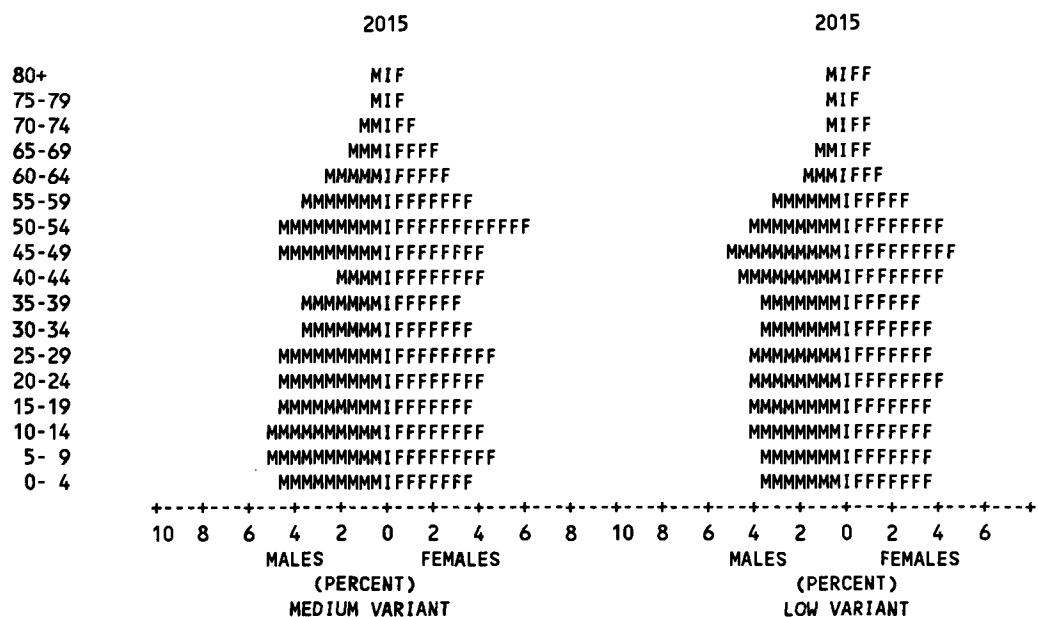

The detailed age-sex breakdown of the population in 1980 and for each of the four variants in the year 2015 is demonstrated in the age pyramids in Diagram 3.

DOMINICA
DIAGRAM 3 : AGE PYRAMIDS 1980-2015

The 1980 pyramid has a modified bell shape. It is widest at age 10-14 and narrows smoothly to age 30-34 above and age 0-4 below. This is consistent with declining birth cohorts (due to a falling fertility rate and/or a declining number of women of childbearing age) during the past ten years, preceded by a 25-year period of increasing birth cohorts. From age 35-39 to 60-64 for males and 65-69 for females, the pyramid narrows only very slowly which could have been the result of a fairly long period of a steady number of births, but is more probably greatly influenced by emigration.

DIAGRAM 3 CONTINUED

This modified bell shape is maintained 35 years later, in the year 2015, in the population now 35 years and older, in all variants, the bands being narrower because of mortality and, to a lesser extent, emigration. Below the age of 35 the pyramids mirror the succeeding 5-year birth cohorts (0-4 years) reduced by mortality and emigration. There is, therefore, little variation in the width of succeeding age groups in 2015 for any of the realistic variants, except for a slight bulge at the age-span 15-29, reflecting the higher number of births in the period 1985-2000. However, the pyramid for the high variant is necessarily widest and that of the low variant narrowest for this age span.

Dependency Ratios

As is evident from the discussion of the changing age structure (above) the dependency ratio will fall steadily and significantly for each variant, as the population of working age increases and the young dependent population falls over time. Starting at 894 (per thousand) in 1980, the dependency ratio is projected to fall, by the year 2000, to 502 for the low variant, and to 576 and 593 respectively for the medium and high variants. Thereafter the ratios converge for the various realistic variants to range between 388 and 413 by the year 2015.

High Variant						

Aging of the Population

There will be an appreciable aging of the population over the projection period. In 1980 the median age of the population was 18.9 years. By the year 2015 the median age, according to the constant variant will have increased to 25.7 years. Since the fertility rate is assumed to remain unchanged in this variant, and relatively few young persons (under 15 years) emigrate, this aging is entirely the result of the reduced mortality.

When the effects of a falling fertility rate is added, the process of aging is much faster for the realistic variants, the median age by the year 2015 ranges from 29.8 years for the high variant to 33.3 years for the low variant.

Sex Distribution

In 1980 there were slightly fewer men than women in the population - 992 males per 1000 females. Since the death rates of males is higher than among females, this is conducive to a reduction in the sex ratio. On the other hand, the emigration rate is higher for women, and hence emigration contributes to an increasing sex ratio.

As is seen in Table 4.6, the effect of the emigration more than offsets that of mortality so that the number of males per 1000 females increases for all variants. Among the realistic variants, the increase in the sex ratio necessarily increases with emigration and is therefore highest for the low variant. The range is, however, small, the ratio being 1027 for the high and 1038 for the low variant. It is slightly higher, again, for the constant variant.

Sex ratios by age are given in Appendix II. For the medium variant for 1980, the males exceed females for ages under 35 years, but the ratios fluctuate, being much lower for age groups 10-14, 15-19 and 30-34 than for the other age groups under 35.

From age 35 onwards, the sex ratio declines except for the groups 55-59 and 65-69 where there is an appreciable increase. By the last closed age group (75-79) there are only 656 males per 1000 females.

If we trace the changes over time for a given age-cohort, we find that, in general, up to age 35-39, the sex ratio increases. Since the death rate for males is higher, this can only be the result of the higher emigration of women. From age 35 and onwards, however, the differential mortality more than offsets differential emigration, and the sex ratio declines steadily. For example, the cohort aged 15-19 in 1980 begins with a sex-ratio of 1037 which increases steadily to 1081 in the year 2000 when the cohort is now 35-39 years old. Thereafter, however, the ratio declines to 993 in 2015.

By the year 2015, because of the slowly declining sex ratios at age 0-4, the ratios will be in general, smaller than at the beginning of the projection period for the population under 30 years of age. At higher ages, however, the sex ratios for 1980 were extremely low, and for most age groups the 2015 ratio will be higher. Males will exceed females for all age groups under 65 years, except 50-54.

The fact that females will be declining as a proportion of the total population may well mean that greater effort will be required to ensure that attention to the needs and welfare of women does not also diminish.

Vital Rates

Although for the constant variant the total fertility rate is assumed to remain unchanged throughout the projection period, because of changes in the age-sex structure of the projected population, the implied crude birth rate (CBR) jumps from 26 for 1980-1985 to 29 for the next two quinquennia and then falls rapidly to 24 from 2000 onwards.

2005-2010	9.88	16.69	6.81	9.12	16.32	7.21
2010-2015	9.64	16.62	6.98	8.07	15.50	7.43
Low Variant						

For the realistic variants, the CBR at the beginning and at the end of the projection period is similar for all variants, ranging between 23 to 25 at the start and 16 to 17 at the end. For all variants, therefore, there is an implied fall by about one-third. In accordance with the assumption, however, the rate of decline is most rapid for the low, and least rapid for the high variant.

Infant Mortality Rates

The infant mortality rate, which is the same for all variants, is about 40 infant deaths per 1000 live births in 1980-1985, and is projected to fall steadily to 22 by the last quinquennium (Table 4.8). What is remarkable is that while the male rate is projected to fall by about 28 percent from 42 to 30 per thousand, the female rate is projected to fall by nearly two-thirds from 38 to 14 per thousand. By the end of the projection period, therefore, if these projections hold, the male infant mortality rate would be nearly 2½ times as high as the female rate.

Reproduction Rates

As we stated earlier, the high, medium and low variants assume a total fertility rate of 2.1 by the years 2015, 2005 and 1995 respectively. With an assumed sex ratio at birth of 1.050, this yields a gross reproduction rate (GRR) of approximately 1.02 by the specified dates.

As is seen in Table 4.9, when allowance is made for mortality among females up to the end of the childbearing period, the net reproduction rate (NRR) will fall to below replacement level (less than 1.0) by 1995 in the case of the low. For the medium and high variants, the NRR is projected to reach replacement level by the end of the projection period.

V - GRENADA

PROJECTION ASSUMPTIONS

Mortality

The average length of life (expectation of life at birth) which was 66.7 years and 73.1 years for males and females respectively in 1980, is assumed to increase by 4½ years for males and over 3½ years for females to 71.2 and 76.8 years by 2010-2015. Because of the slower rate of improvement for females, the excess of females over males is assumed to fall from 6.4 to 5.5 years over the projection period.

Low	-8000	-7333	-6666	-5999	-5332	-4665	-4000

Fertility

The total fertility rate (TFR) was 3.4 in 1980 and is kept at this level throughout the projection period for the constant variant. For the realistic variants it is assumed that the TFR will fall to replacement level (2.1) by 2010-2015 for the high, 2005-2010 for the medium and 1995-2000 for the low variants respectively, and remain constant thereafter. For the first quinquennium 1980-1985 the TFR is taken as 3.2 for the high and medium variants, and 3.1 for the low.

Migration

Net emigration is assumed to have been 8000 for the 5-year period 1980-1985, and it is assumed that this number will have fallen by one-half to 4,000 in the last 5-year period, in the case of the low variant, and 5 and 15 years earlier, respectively, for the medium and high variants. In each case it is assumed that emigration will remain constant at 4,000 per 5-year period to the end of the projection period.

ANALYSIS OF RESULTS

The Total Population

The projections emphasize the importance of migration for population growth in that if both fertility and migration were to fall to the extent assumed for the high variant by 1995 the population would be higher than if both components remained unchanged (constant variant). The projections range from a low of 92,000 to 110,000 with the constant variant at 103,000.

The implied rate of growth is appreciably lower for the first quinquennium than for the second in all variants except the low, though in no quinquennium will it reach 1 percent per annum. For the high variant the rate of growth will increase from 0.2 percent in 1980-1985 to 0.8 percent in 1995-2000 and then fall again to 0.3 percent by 2010-2015. According to the medium variant the highest rate of growth will be 0.4 percent in the second and third quinquennia, and 0.2 or 0.3 percent for the rest of the projection period. For the low variant the rate of growth will range between -0.1 and 0.2 percent. If fertility and migration were to remain constant, the population would grow by 0.3 to 0.5 percent per annum.

At the very low rate of growth in the first quinquennium, the population would take 345 years to double itself, according to the high and medium variants, and 690 years for the low variant.

N.A.= Negative Growth or Zero Growth

The Components of Population Growth

The total population growth (numbers) is lowest in the first quinquennium for all variants except the low. For all variants the growth (numbers) will rapidly rise to a maximum and then decline. In the case of the low and constant variants there will be an upswing in the last quinquennium. The low variant projects a loss in each of the three quinquennia covering the period 1995-2010.

The small growth in the first quinquennium is largely accounted for by the high emigration, and the projected increasing growth in the high and medium variants to the year 2000 and 1995 respectively, is again because of falling emigration.

The number of births is projected to be very slightly higher in the second than in the first quinquennium for the high and medium variants, but apart from these and the last quinquennium for the medium variant where no change is projected, the number of births will fall throughout the period for the three realistic variants.

For the high variant the number of births in 2010-2015 will be about 680 per year, less than in 1980-1985, while for the low variant it will be about 950 per year less. The number of deaths, starting at about 700 per year in 1980, is projected to fall to slightly less than 700 per year for the high and 600 per year for the low variants.

Age Distribution

As is seen in Table 5.4, the pattern of growth, for the realistic variants, with only negligible exceptions for the 0-4 and 15-24 age groups is that the age group 25-64 years, consisting of the population of mature working age, will steadily and significantly increase as a proportion of the total, while all other age groups decline.

The age group 15-64 years is projected to increase from 31 to 53-56 percent. After very slight increase, the pre-school population (aged 0-4 years) will fall from 12 to 8 percent, and the old age dependent population (65 years and over) is projected to fall

* Due to rounding figures may not add to 100

slightly from 7 to 5-6 percent of the total. The school age population (5-14 years) and the young adult (inexperienced labour force) age groups (15-24 years) are of roughly equal size, and are both projected to fall from 26 and 24 percent respectively to 15-17 percent.

Table 5.5 uses index numbers to demonstrate the rates of growth of the five age groups. The population of mature labour force age will increase steadily, and by the end of the projection period will be more than twice as large as in 1980 according to the high variant and nearly twice as large for the medium.

According to the medium variant, the pre-school population will grow at first but by 2015 will have fallen to less than three-quarters the 1980 population. The school-age population will fall most, and by 2015, according to the medium variant, will be only two-thirds the 1980 population. The young adult and the old-age dependent populations will be both in the vicinity of 80 percent of the 1980 size by 2015.

2000-2005	80	81	86	165	90	69	67	78	163	89
2005-2010	72	73	87	181	84	66	59	74	176	82
2010-2015	72	64	80	198	83	63	57	63	188	81

The major area of concern, therefore, is with regard to the population of mature working age. The labour force may well double in the 25-year period of the projections, and so must the job opportunities or unemployment could become extremely serious. On the other hand, the need to provide for education and training (ages 5-14 and 15-24 years) as well as for the dependent old and the pre-school populations will all be significantly reduced.

Dependency Ratios

From the foregoing discussion of the change in the age structure, it is clear that the dependency ratio will fall very significantly for all variants. The dependency ratio of 851 in 1980 falls steadily to 396 and 405 for the low and medium variants and to 426 for the high variant.

GRENADA

Low Variant					

Sex Distribution

In 1980 there were 923 males per 1000 females in the total population. According to all variants, males are projected to exceed females by the year 2000. The increase in the sex ratio is fairly steady over the projection period.

The population is projected on the assumptions that there will be slightly more male than female births (1030 sex ratio at birth), and that more females than males will emigrate (754 males per 1000 females). The resulting surplus of males is slightly reduced by the higher male death rate.

In general, cohorts over 45 in 1980 (Appendix II) experience a declining sex ratio over time because of the higher male mortality rate. For example, for the medium variant, the cohort aged 50-54 in 1980 had a sex ratio of 784 in that year, 735 in 1990 and 562 in 2005 by which time the cohort would be 75-79 years old. On the other hand, with few exceptions, the cohorts under 45 in 1980 experience an increasing sex ratio up to about age 50 when the influence of emigration becomes less important.

For example, the cohort aged 5-9 in 1980 starts with a sex ratio of 1030 but this is projected to increase to 1165 by the year 2015 when the cohort will be 40-44 years old. For the three cohorts covering the age span 10-24 years the sex ratios increase only up to age 40.

As a result of these changes in the cohorts, while males exceeded females in 1980 only among young persons under age 15 and in the 25-29 cohort, by the year 2015 all but one of the cohorts under age 70 years are projected to have more males.

The fact that females will decline as a proportion of the total population does not in any way diminish the need for continued and increased attention to be paid to the special problems facing women and to improving their status and welfare in society.

Vital Rates

As is shown in Table 5.7, the projections imply that there will be a small decline in the crude death rate from 8 to 6 per thousand in all variants. The fall in the crude birth rate is projected to be much larger, the CBR falling from 27 to 16-17 over the whole period in the case of the three realistic variants, and to 24 for the constant. The infant mortality rate (Table 5.8) is also projected to fall significantly from 21 to 12 infant deaths per 1000 live births, the female rate falling from 16 to 9 and the male from 26 to 16.

PROJECTION ASSUMPTIONS

Mortality

In the absence of adequate mortality data, the mortality schedule and life table for Saint Christopher and Nevis have been used for the Montserrat projections.

The average length of life (expectation of life at birth) was 62.8 for males and 67.9 for females in 1980, and will, according to the assumptions for these projections, increase by 3½ and 7½ years respectively over the projection period. For the period 2010-2015, therefore, the assumed average length of life is 66.4 and 75.4 years respectively. The excess of females over males is therefore assumed to increase from 5 years in 1980 to 9 years by 2010.

MONTserrat

Low	-750	-656	-562	-468	-375	-375	-375

Fertility

At 2.4 in 1980, the total fertility rate (TFR) was only slightly higher than replacement level (2.1). It is assumed that the TFR will fall slowly to replacement level by 2010-2015, 2000-2005 and 1990-1995 respectively for the high, medium and low variants.

Migration

It is estimated that net emigration is about 750 per 5-year period at the beginning of the projection period and that it will decline. The most rapid decline, for the high variant, is to zero by the year 2010. For the medium and low variants it is assumed that emigration will fall to one-half by 1990 and 2000 respectively, and will, in each case, remain constant thereafter.

ANALYSIS OF RESULTS

The Total Population

If there is no reduction in emigration and fertility remains unchanged (the constant variant), the population of Montserrat is projected to fall from 11,600 in 1980 to a mere 9,100 in 2015. Even if migration falls by one-half, as in the low and medium variants, the population is still projected to fall, though somewhat less, to 10,300 and 11,200 respectively. Such a decline in total population would be in accordance with the pattern in recent decades. Only the high variant projects an increase to 12,200 (Table 6.2).

The constant and low variants both envisage a continuous decline over the whole projection period. In the case of the low variant, the rate of decline is projected to be 0.7 percent in the first quinquennium but will fall rapidly to only 2 percent from 1995 onwards. In the case of the constant variant the rate of decline is projected to increase from 0.4-0.6 percent up to 2000, to 1.0 percent by the end of the projection period. According to the high variant, the population will decline at first, the rate of decline being 0.7 percent in the first and 0.3 percent in the second quinquennia. It will then increase from 2000 onwards, very slightly at first (0.1 percent) but rapidly in successive quinquennia to 0.7 percent in the last period.

N.A = Negative Growth or zero growth

The Components of Population Growth

From Table 6.3, it is clear that the number of deaths is even more important than emigration as a contributor to population decline or a restraint on population growth. Except for the constant variant, the number of deaths exceeds the number of emigrants, and keeps natural increase low, ranging from 58 to 64 percent of births.

Low Variant								

Age Distribution

As is seen from Table 6.4, the mature adult age group (25-64 years) is the only one which is projected to increase steadily over the projection period. This will increase very appreciably, according to all variants, from 36 percent in 1980 to 53-56 percent in 2015. The youngest, pre-school age-group is projected to increase very slightly at first, from 8 to 10 percent, and then to fall slowly back to 7-8 percent by 2005.

Young adults (15-24 years of age) are projected to fall quickly from 20 percent of the total in 1980 to 14 percent in the year 2000 in the three realistic variants, then rise slightly to 15-17 percent, and then fall very slightly again in the last quinquennium.

The population of school age (5-14 years) and the old dependent population (65 years and over) are both projected to fall significantly, the former from 23 to 14-15 percent over the projection period, and the latter 13 to 8-9 percent.

*Due to rounding figures may not add to 100

From Table 6.5, the medium variant is used to demonstrate the differential rates of growth of the five age groups. The group of mature working age (25-64 years) is projected to grow steadily to 48 percent above the 1980 figure. All other age groups are projected to fluctuate but to be appreciably smaller in 2015 than in 1980. The pre-school population will grow at first to reach 15 percent above the 1980 figure in 1990, but by 2015 it will be only 86 percent of the 1980 figure. The school-age population and the old dependent population are projected to decline most, to 58 and 61 percent respectively in 2015. The young adult population will also increase at first, but will be less than three-quarters of the 1980 figure by the end of the projection period.

2010-2015	86	58	73	148	61	76	53	65	139	60

The pattern for the other variants is the same, differing only in the size of increase or decline of the various age groups. For example, the population of mature working age is projected to be 62 percent higher in 2015 than in 1980 in the case of the high variant, and 39 percent in the case of the low variant.

It is clear, then, that the principal consequence of the projected population growth over the 25-year period after 1980, will be an appreciable increase in the population of adult working age, and hence a potential large increase in the labour force. This in turn will require a large expansion in the economy and in the number of new jobs if unemployment and underemployment are not to increase to unacceptable levels.

The demands usually associated with rapid growth in the other age groups of the population will, according to the projections, tend to be lessened. Thus, again referring to the medium variant, the need to provide maternal and child care will increase by about 15 percent by 1990 but thereafter will fall steadily.

The demands of the population of school-age for school places, teachers and related resources and services, will steadily reduce, so that the existing provisions will appreciably exceed the demand in the not-too-distant future. Similarly, the young adult population, with its very high level of unemployment and its related need for occupational training, is projected to fall to only three-quarters the 1980 figure and, presumably, these and other problems related to youth should also fall. Finally, the severe problems of providing adequately for the aged population should be much less pressing, getting steadily less serious over the projection period, except for the last quinquennium.

Dependency Ratios

As is evident from the preceding discussion, the dependency ratio is projected to fall appreciably according to all variants. The fall is greatest for the low variant. Starting at 800 dependents per 1000 persons of working age, the ratio falls, by the year 2015, to 419 for the low and 433 for the high variants; with only one exception - the year 1995 - the decline is continuous for all variants.

2015	422.5	100.0	34.36	418.5	101.1	35.81
Low Variant						

Aging of the Population

The median age of the population, already high at over 24 years in 1980, is projected to increase to 33 years for the high and 36 years for the low variant. This aging is the result of the increasing longevity on the one hand, and the declining fertility for the realistic variants on the other. Since emigration is assumed to be much more prevalent among younger than older persons, high emigration is conducive to greater aging. This explains the higher median age of the low variant. It also explains why the median age of the low variant population is projected to increase by 5 years between 2000 and 2015 while the increase for the high variant is projected to be only 2½ years.

Vital Rates

According to the projections, both the crude birth and crude death rates will fall between 1980 and 2015, the death rate experiencing the larger relative decline. For the medium variant, for example, the CBR will fall by 23 percent from 20.0 to 15.4 per thousand, while the CDR will fall by 33 percent from 13.6 to 9.1 per thousand.

Low Variant						

Infant Mortality Rates

The infant mortality rate (IMR) in 1980 was the highest in the region at 40 infant deaths per 1000 live births. It is projected to fall steadily over the projection period to just over one-half -22 per thousand - by 2015.

MONTSERRAT
TABLE 6.8 : INFANT MORTALITY RATES
(PER 1000 BIRTHS)

Five Year Period	Males	Females	Total
1980-1985	42.22	37.59	39.93
1985-1990	39.82	30.70	35.30
1990-1995	37.65	25.49	31.63

2000-2005	33.69	18.15	26.00
2005-2010	31.92	15.60	23.84
2010-2015	30.47	13.78	22.21

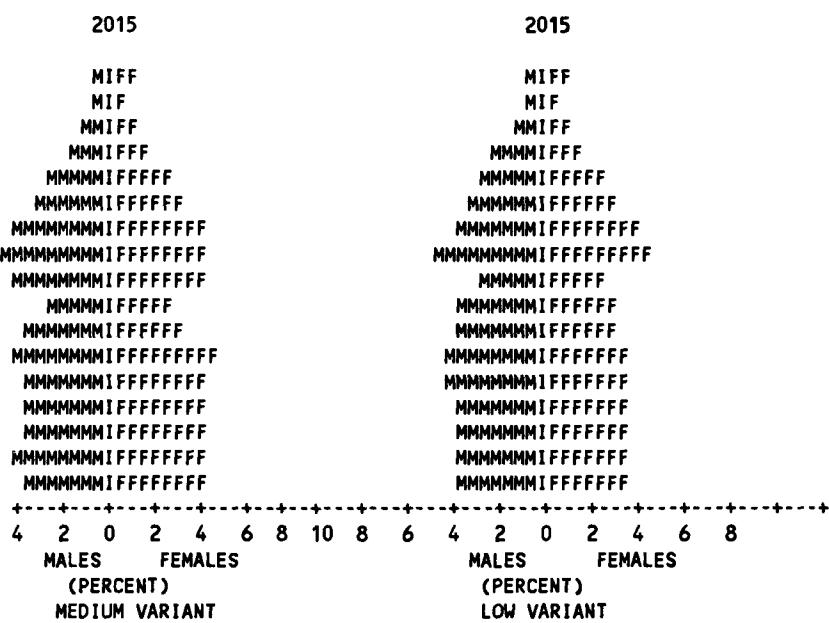

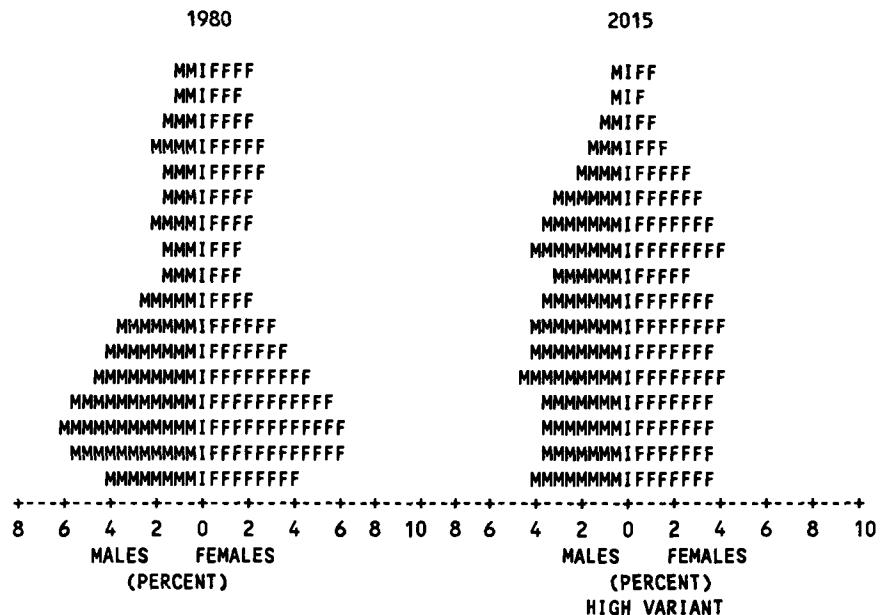

Reproduction Rates

The gross reproduction rate (GRR) assumed for 1980-1985 ranged from 1.13 for the low to 1.16 for the high and medium variants. It is assumed that this will fall to 1.04 by 1990 in the low and 2010 in the high variants respectively. When account is taken of mortality among females, the net reproduction rate (NRR) is projected to fall slightly. In the case of the medium variant this fall is from 1.15 to 1.04. For the medium and low variants the NRR will fall to almost 1.00 before rising again slightly.

PROJECTION ASSUMPTIONS

Mortality

The average length of life (expectation of life at birth) which averaged 62.8 years for males and 67.9 years for females during 1980-1985, is projected to increase by 3½ years for males and 7½ years for females to 66.4 and 75.4 years respectively by 2010-2015. In 1980-1985 the average length of life of females exceeded that of males by 5.1 years; by the end of the projection period it is expected to be 9 years higher.

Medium	-4000	-3600	-3200	-2800	-2400	-2000	-2000
Low	-4000	-3667	-3334	-3001	-2668	-2335	-2000

Fertility

The total fertility rate in 1980 was 3.4 children per woman. It is assumed that the TFR will be 3.3 during the first quinquennium 1980-1985, and that it will fall to replacement level (2.1) during the projection period. The quinquennium in which the TFR will reach replacement level is assumed to be 2010-2015, 2005-2010 and 1995-2000 for the high, medium and low variants respectively. In each case the TFR is kept at replacement level for the remainder of the projection period.

Migration

It is assumed that the net number of emigrants in the period 1980-1985 will be 4,000, i.e. 800 per year and that it will decline to one-half - 400 per year, after which it will remain constant. This lower limit will be attained, according to the high, medium and low variants by 1995, 2005 and 2010 respectively.

ANALYSIS OF RESULTS

The Total Population

In 1980 the population of St. Christopher and Nevis was 44,400. According to the low variant, the population will decline steadily over the projection period to 41,600 in 2015. The medium and high variants both project a small decline in population in the first 5-year period, but a small increase thereafter, to 45,600 and 49,800 respectively. The constant variant, with its high emigration, projects an increase in population between 1985 and 2000 but a slight fall in the other periods, resulting in a 2015 population only slightly larger than that of 1980.

For all variants the rates of change will be small. For the low variant annual average rates of change will be negative, but being highest in the period 1995-2000 - 0.4 percent, and only 0.1 to 0.2 percent in the other 5-year periods. The high variant will increase in all 5-year periods except the first (1980-1985), the annual rates of increase ranging between 0.2 and 0.6 percent. For the constant and medium variants, after a decline in the first quinquennium the population is projected to increase by not more than 0.1 percent per annum for the remainder of the projection period in the case of the medium variant, and for the period 1985-2000 for the constant variant.

N.A. = Negative Growth or Zero Growth.

The Components of Population Growth

Over the 35-year projection period 1980-2015, according to the medium variant the number of births will be about 34,700 and the number of deaths 13,400, giving a natural increase of 21,400. Net emigration, however, is assumed to be 20,000, and the total population is therefore projected to rise by a mere 1,400.

It is interesting to look at the relationship between births, deaths and net emigration in Table 7.3. The death/birth ratio is 0.37 for the high, 0.38 for the medium and 0.42 for the low variant. Despite these high ratios, net emigration will be very much higher than deaths for every variant; the ratio of emigrants to deaths being 1.3, 1.5 and 1.6 respectively for the high, medium and low variants.

For all the realistic variants the number of births will fall steadily over the projection period. The decline between successive 5-year periods is projected to be appreciable except between the first two intervals for the high variant, and the last two for the medium variant. In the case of the medium variant, the number of births was 6,200 in 1980-1985 and will be 3,800 in 2010-2015.

The number of deaths will also fall steadily over the projection period for each of the variants. The number of deaths is projected to fall from about 2,450 in the first 5-year period to between 1,500 and 1,600 by 2010-2015.

Low Variant								

Age Distribution

At the outset, the youngest age group (0-4 years) was slightly larger than the oldest (65+ years) - 12 as against 10 percent. The school-age (5-14 years) and young adult (15-24 years) populations were roughly the same size, each with about one-quarter of the total population, while the population of mature working age was somewhat larger (29 percent).

The pattern of growth over the projection period is simple and quite uniform for the various age groups. The population of mature working age is the only one that will increase, and this it does consistently, rising from 29 to 54-58 percent for the realistic variants,

* Due to Rounding figures may not add to 100

and to 48 percent for the constant. The other age groups all decline, as a proportion of the total population, the decline being fairly consistent in all instances. By the end of the projection period, the school and young adult populations remain roughly equal, each at 15-17 percent of the total. The pre-school population will fall to 8 percent and the old-age dependent population will be about one-half this - 4 percent.

As is seen in Table 7.5, the relative increase in the population of mature working age at the expense of the other age groups will come about because this is the only age group which will increase at any time during the projection period, the population in 2015 being 92 percent higher than in 1980 for the medium variant and more than twice as large for the high variant. On the other hand, the pre-school and school-age populations are projected to be only two-thirds of the 1980 populations, and the young adults about three-quarters. The old-age dependents will decrease to only 41 percent.

2010-2015	68	63	74	192	42	60	56	57	186	41

The likely consequences of these differential rates of growth are that there will be a great deal of pressure from the population of mature working age for jobs while the pressure from the other age groups will all decline. Thus the number of jobs should be doubled in the 35 years following 1980 or unemployment and under-employment may rise to serious levels.

On the other hand, the demand for resources for the aged population will be halved, and the needs of young persons, for pre-school and school facilities as well as for vocational training, will all be greatly reduced.

The detailed 5-year breakdown (Appendix 1) gives a good indication of how the trends in the major age groups will come about. Dealing first with the decline over time in the number of persons of school and pre-school age: since the number of births will decline in each successive quinquennium (Table 7.3), for the most part so will the 0-4 age group, except at the beginning of the projection period in the case of the high, and to a lesser extent the medium variant. Moreover, in 1980 the first three 5-year age groups are in ascending order of size, and this, along with the declining number of births, will result in the numbers in each of these 5-year age groups declining over time for most of the projection period.

At the other extreme, given the age structure in 1980, the number of persons aged 65 years and over will fall in each of the 5-year age groups over most of the projection period. For example, the 1,657 persons aged 60-64 in 1980, will fall by 1985 to 1,432 because of deaths, and further to 1,365 because of emigration. The projected population aged 65-69 will, therefore, fall from 1,536 in 1980 to 1,365 in 1985. And this is the pattern for most years and most of the 5-year age groups covering persons 65 years and older, given the age structure of the population 30 years and older in 1980.

On the other hand, the population aged 20-24 in 1980 is so much less than the 15-19 age group that even with the loss due to mortality and migration, the population aged 20-24 in 1985 will be appreciably greater than in 1980. This holds also for the age range 15-29 in 1980 which ages to 50-64 in 2015. This wave of increases and the relatively small declines at older ages again because of the 1980 age structure, more than offset the fall in the other age groups and results in the increasing population 15-64 years old.

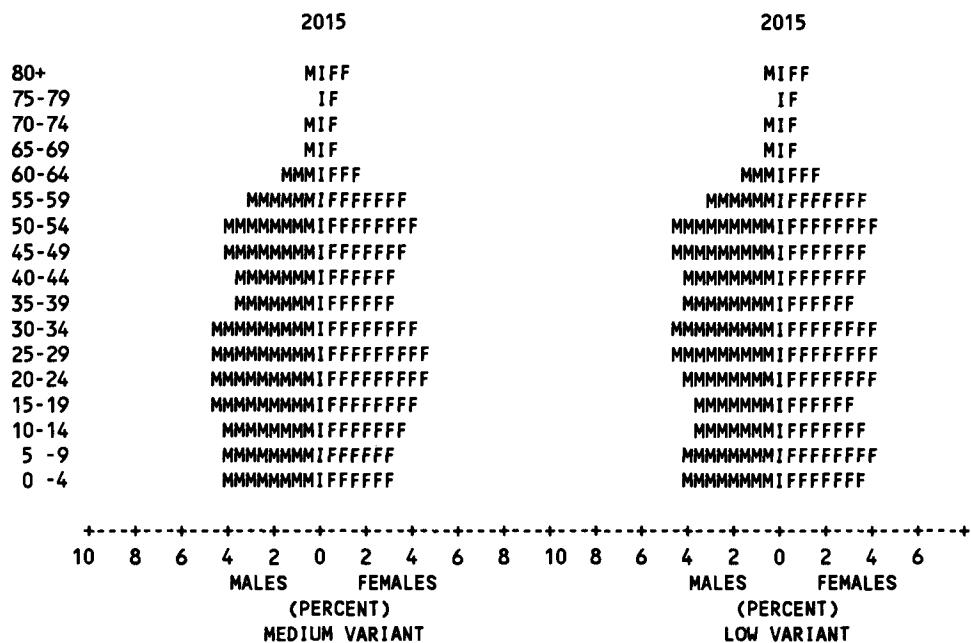

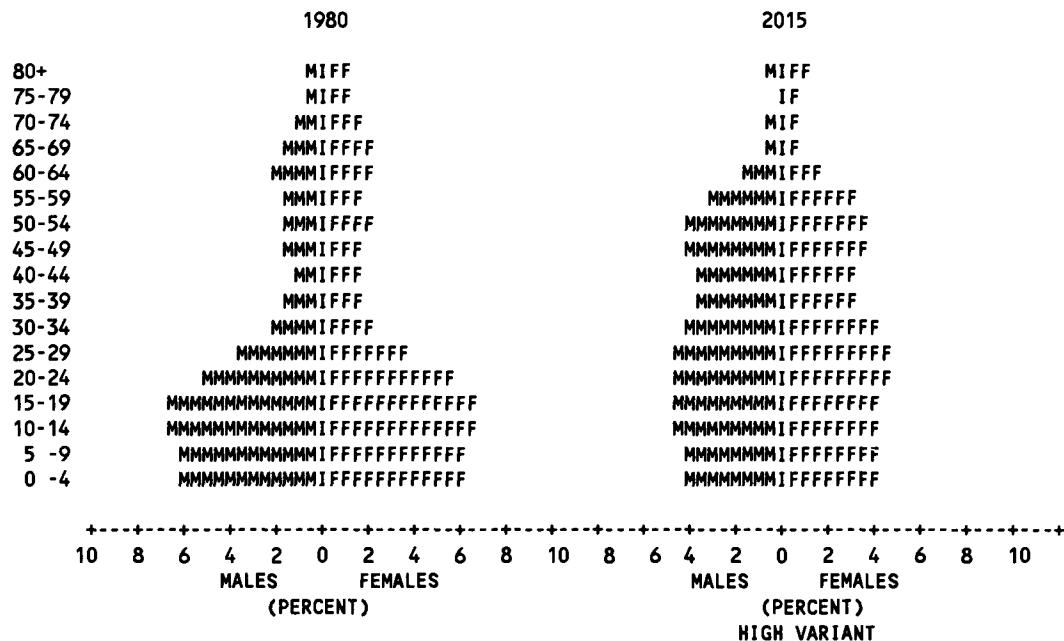

The age structure in 1980, which we have been discussing, is well demonstrated in Diagram 6. At the base of the pyramid, the population under 20 years of age does not differ much from one 5-year age group to another though the pyramid widens very slightly with age. For the age span 20-44 years, however, the pyramid narrows rapidly, and then there is a bulge, the pyramid widening to age 60-64 and then narrowing again.

By the year 2015, there is expected to be little variation between the 5-year age groups covering the age span under 35 years. There will then be a narrowing of the pyramid at age 35-39 followed by a widening to age 50-54 and a rapid narrowing at higher ages, mirroring the shape of the 1980 pyramid when the cohorts were 35 years younger.

Dependency Ratios

The shifting age structure described at the beginning of the preceding section will necessarily result in a large, rapid and continuous decline in the dependency ratio. In 1980, there were 882 young and old-age dependents per 1000 persons of working age. By 2015, this ratio will fall to 370 for the low and 404 for the high variants, and will be 380 for the medium variant.

Low Variant						

Aging of the Population

Despite the decline in the old population 65 years and over, the population is projected to age from just under 20 years in 1980 to about 30 years according to the high and medium variants, and to 32 years, for the low variant.

Sex Distribution

There were fewer males than females (923 per 1000) in 1980, but by 2015 it is projected that males will exceed females by about 1050 to 1000, according to the medium variant. The projected sex ratio is 1060 for the high variant, and 1030 for the low.

As is seen from Appendix II, in 1980 males exceeded females for three of the four 5-year age groups under 20 years, but there were more females in all age groups 20 years and over, the surplus of females being especially large among persons 75 years and over.

With an assumed sex ratio at birth of only 1030, and the more rapid improvement in female mortality, the sex ratio for the youngest 5-year age group, which was 1024 in 1980, is projected to fall steadily over the projected period, to 1009 in 2015.

However, there are more female than male emigrants, and among young persons under 40 years old, the impact of emigration offsets the higher mortality among males. As a result, for each age cohort under 30 years in 1980, the sex ratio increases with age (diagonally) to age 39. For the 30-34 cohort, the increase continues to age 54. For the younger age cohorts, i.e. those aged 0-4 in 1985 and later, the sex ratio increases throughout the projection period.

Above age 35, however, the influence of mortality is greater than that of emigration, and the sex ratio declines with age for each age cohort with the exception of the cohort aged 30-34 in 1980 (see above) and the cohort aged 25-29 in 1980 for which the increase continues to age 44.

As a consequence, it is projected that by the year 2015 males will exceed females in all age groups under 70 years with the single exception of the 55-59 which, according to the 1980 population figures, had a quite low sex ratio (927).

This projected decline in the relative number of females, along with the increasing number of persons of mature working age and the related problems of unemployment and underemployment could lead to a shift of attention away from the special needs and problems of women. To ensure continued action aimed at improving the status and welfare of women despite this reduction in their relative numbers, programmes to this end may have to be continued and intensified.

Vital Rates

The crude birth rate will fall steadily according to each of the three realistic variants. Although the total fertility rate is projected to fall to replacement level by 1995 in the case of the low variant, and remain constant thereafter, the CBR will continue to fall, though somewhat more slowly, throughout the projection period. For this variant, the CBR will fall from 28 per thousand for 1980-1985 to 18 by 1995 and 16 by 2010-2015. The pattern is similar for the other two realistic variants, the fall being from 28 to 17 for the medium and high variants.

The crude death rate is projected to drop steadily from 11 to 7 per thousand. The net result will be a fall in the natural rate of increase from 17 to 10 per thousand for the high and medium variants and to 9 for the low variant.

SAINT CHRISTOPHER AND NEVIS
TABLE 7.7 : VITAL RATES (PER 1000)

Five Year Period	Natural Increase Rate	Crude Birth Rate	Crude Death Rate	Natural Increase Rate	Crude Birth Rate	Crude Death Rate

2010-2015	10.13	16.92	6.79	9.12	16.31	7.18
High Variant						
Low Variant						

Infant Mortality Rates

The infant mortality rate of 40 (infant deaths per 1000 live births) is projected to fall by nearly one-half during the projection period to 22 in 2010-2015. At the outset the female rate was slightly lower than the male rate (38 as against 42). By 2010-2015, however, the assumed mortality schedule projects that the female rate will be less than one-half that of the male - 14 as compared with 30.

SAINT CHRISTOPHER AND NEVIS
TABLE 7.8: INFANT MORTALITY RATES
(PER 1000 BIRTHS)

Five Year Period	Males	Females	Total
1980-1985	42.22	37.59	39.94
1985-1990	39.82	30.70	35.33
1990-1995	37.65	25.49	31.66
1995-2000	35.60	21.30	28.55
2000-2005	33.69	18.15	26.03
2005-2010	31.92	15.60	23.88
2010-2015	30.47	13.78	22.25

Reproduction Rates

Given the assumed sex ratio at birth of 1030 males per 1000 females, the replacement TFR of 2.1 is equivalent to a gross reproduction rate (GRR) of 1.03. In the case of the low variant, this is associated with a net reproduction rate (NRR) of 1.0 in 1995-2000 which increases very slowly to 1.01 by the end of the projection period. This compares with a NRR of 1.5 in 1980-1985. For the medium and low variants the NRR which is about 1.5 at the outset, will also be 1.01 in 2010-2015, falling steadily over the projection period.

VIII - SAINT LUCIA

PROJECTION ASSUMPTIONS

Mortality

The average length of life (expectation of life at birth) is projected to increase from 67.0 years for males and 72.6 years for females in 1980-1985 to 70.1 and 76.3 respectively by 2010-2015, an increase of 3.1 years for males and 3.7 years for females. The excess of female expectancy is 5.6 years in 1980-1985 and is projected to increase slightly to 6.2 years by the end of the projection period.

Low	-3500	-3208	-2914	-2624	-2332	-2040	-1750

Fertility

The total fertility rate was 4.1 in 1980 and is assumed to remain at this level during the first quinquennium 1980-1985. Thereafter the TFR will fall to replacement level (2.1) by 2010-2015 according to the high variant, by 2005-2010 according to the medium, and by 1995-2000 according to the low variant. In each case the TFR will remain, according to the assumptions, at replacement level for the remainder of the projection period.

Migration

There were about 700 emigrants (net) in 1980. It is assumed that this average annual emigration will continue for the 5-year period 1980-1985 - a total of 3,500 emigrants. The 5-yearly emigration is then assumed to fall to one-half - 1,750 by the 5-year period 1995-2000 for the high variant, 2005-2010 for the medium and 2010-2015 for the low variant.

ANALYSIS OF RESULTS

Total Population

In 1980 the population of St. Lucia was 123,800. According to the realistic variants, by 2015 this population will have increased to between 206,700 (low) and 233,600 (high), the medium or most likely population being 219,200.

According to all three variants, the rate of population growth is projected to be 2.1 percent per annum in 1980-1985 and to decline steadily to 1.1 percent per annum in 2010-2015 according to the medium and low variants, and 1.2 percent for the high variant. Of course the rate of growth will decline most quickly for the low variant. By 1995, for example, the rate of growth is projected to be 2.2, 1.9 and 1.6 percent for the high, medium and low variants respectively.

The Components of Population Growth

Over the 35-year period 1980-2015, the population will grow, according to the medium variant, by 95,600, while the high and low will grow by 109,900 and 83,100 respectively.

The growth in the first quinquennium is projected to be the same -13,800 - for each of the variants. It is also projected to increase at first and then decline in all cases to between 11,100 (low) and 13,100 (high). However, the decline will begin at different periods - 1990 for the low, 1995 for the medium and 2000 for the high variant. In the case of the high variant the quinquennial growth will exceed 18,000 before declining, while for the low variant it is not projected to rise above 14,200.

The predominant determinant of the population growth is the number of births which is projected to be between 133,800 and 158,900. Here again the quinquennial number of births increases at first and then declines and, in fact, it is this movement of the births that largely determines the similar trend in the total population growth.

Low Variant								

The number of births, which is projected to be 21,500 in the first 5-year period will, according to the medium variant, be 22,300 in the period 1990-1995, after which it will fall steadily to 18,700 in 2005-2010 and then increase slightly to 19,500 in the following quinquennium. In the case of the low variant, the number of births is lowest in 1995-2000 (16,400) and will increase quickly to 18,400 in 2010 and remain at this level in 2015. This somewhat surprising upturn in the number of births after the TFR has reached replacement level is accounted for by the higher population, as is evident from Appendix 1.

The total number of deaths over the 35-year period is projected to be between 32,400 (low) and 33,200 (high). The number of deaths will increase from 4,200 in 1980-1985 to between 5,500 and 5,700 by 2010-2015, the falling mortality rate being offset by the increasing population.

There will be 17,500 net emigrants over the projection period according to the medium assumptions, as compared with 18,400 for the low and 15,800 for the high.

Age Distribution

According to Table 8.4, in 1980 the population of mature working age (25-64 years) and the population of school age (5-14 years) were roughly equal in size, being 28 and 29 percent of the total respectively. The young adult population (15-24 years of age) was 22 percent, the pre-school population was less - 15 percent, while only 6 percent of the total were in the old-age dependent age-span.

During the projection period only the population of mature working age will increase its relative share of the total, the other two adult groups - the young adults and the old-age dependents - will both suffer a small relative decline, while the populations of school and pre-school age will decline more significantly.

* Due to rounding figures may not add to 100

By 2015 it is projected that the population of mature working age will be one-half of the total in the case of the medium variant, and 48 and 53 percent respectively for the high and low variants respectively. The population of school age, which was roughly equal to the 25-64 group in 1980, will be only about one-third the size of that group in 2015, being about equal in size to the young adult group. The pre-school group will have fallen from 15 to 9 percent, and the old-age dependents from 6 to 4.5 percent.

Table 8.5 uses index numbers to show that in actual numbers all age groups will, in fact, be larger at the end than at the beginning of the projection period, except for the pre-school and the school-age populations in the case of the low variant. However, while according to all variants the population of mature working age will more than treble in the 35-year period, in the case of the realistic variants the school and pre-school populations will either be less or only slightly greater than at the beginning except for the high variant where the school-age population is projected to be 22 percent larger. For the medium variant the young adult population will be 53 percent larger and the old-age dependent group 43 percent larger in 2015 than in 1980.

2010-2015	101	104	153	319	143	95	95	124	317	142

According to the realistic variants, the age groups covering the population 15 years and older, except for the 15-24 group in the low variant, will increase steadily over the projection period for all three variants. The other age groups increase at first but then decline somewhat later in the projection period.

These differential rates of growth imply that the resources required for the pre-school and school populations, in terms of maternal and child care and the provision of education facilities, will increase at first but decline later and be not much different in 2015 from in 1980. There will be greater pressure from both the young adult population, for vocational training, for example, and from the old-age dependents. But by far the greatest pressure will come from the population of mature working age, which will require a tripling in the number of jobs in the 35-year period to avoid a serious worsening of the unemployment, underemployment and related problems.

The breakdown of the population by sex and 5-year age groups is well demonstrated in Diagram 7 which gives the age pyramid for 1980 and for each of the variants for 2015.

SAINT LUCIA
DIAGRAM 7 : AGE PYRAMIDS 1980-2015

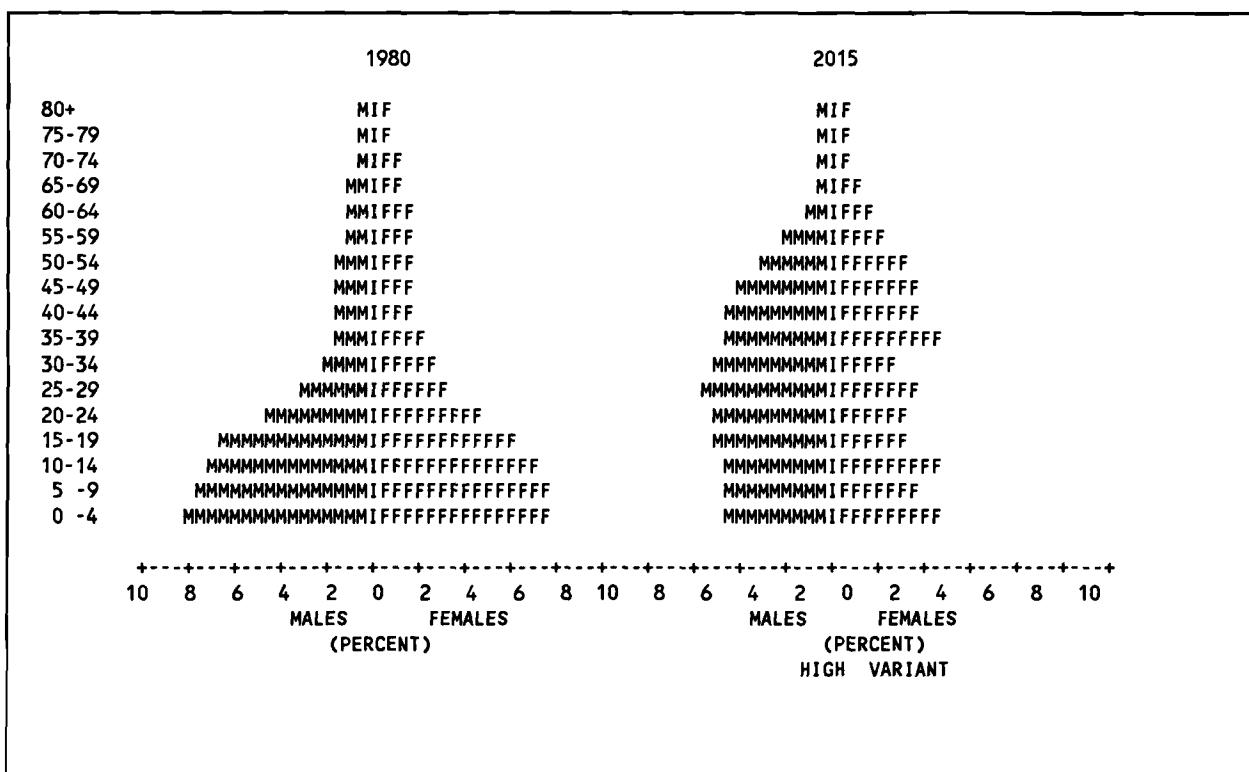

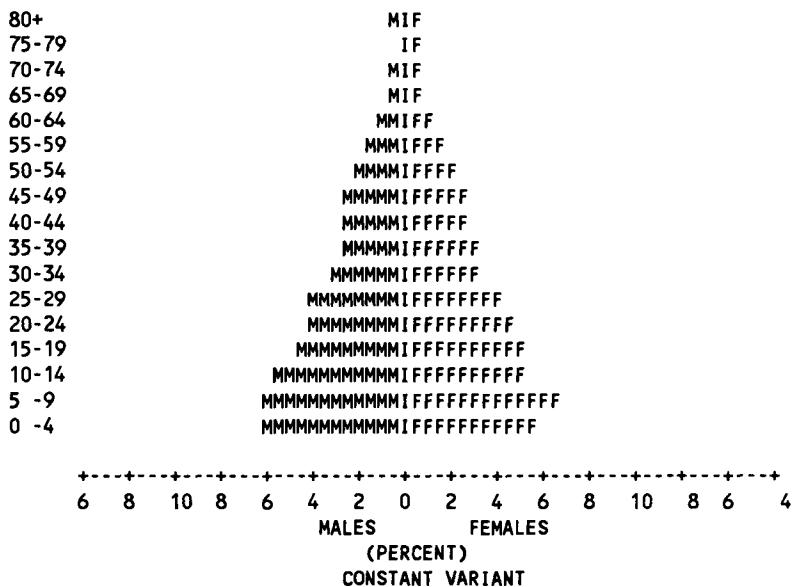

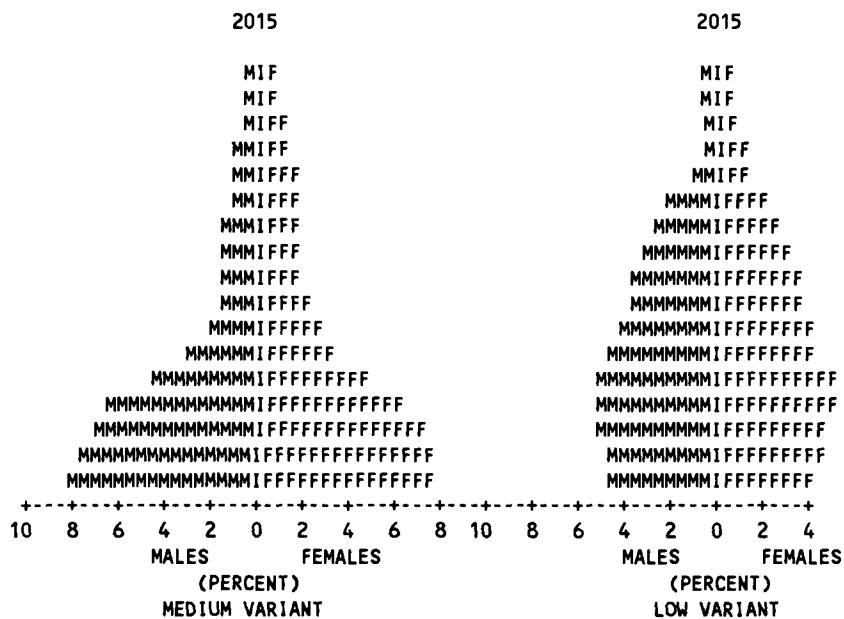

DIAGRAM 7 - CONTINUED

The 1980 pyramid has the traditional bell-shape, the population under 40 years old increasing for each successive younger age group, while for ages 40 years and over there is only a very slow reduction in size.

By 2015, however, the medium and high variants are bottle-shaped, with a narrow neck (age 65 years and over), and a body (under 65 years) which bulges at the centre, being largest at age 20-24, and declining smoothly for both higher and lower ages.

The shape of the pyramid for the low variant is similar to the other two for age 20-24 and upwards. Below this age group, however, each age group is slightly larger than the older. This is in accordance with the increasing number of births from the year 2000 onwards for this variant, which has already been discussed.

Dependency Ratios

In the light of the above changing age structure, while the dependent age population (0-14 and 65+ years) was almost the same as the population of working age in 1980, the dependency ratio is projected to fall from 1,004 in 1980 to 435 in the case of the medium variant, and to slightly less (431) and somewhat more (466) for the low and high variants respectively. As shown above, this decline is mainly due to the fall in the young dependent population.

Aging of the Population

The changing age structure, with the larger decline in the proportion of the population under 15 years old, will result in an increase in the average age of the population, the median age rising from 17 years in 1980 to 27 years for the high and 30 years for the low variant.

Sex Distribution

There were 943 males per thousand females in the total population in 1980. According to the projections, the sex ratio will increase slowly but steadily to about equality from 2005 onwards.

The sex distribution for all variants are given in Appendix II. For the medium variant, we can trace the change in sex distribution for each 5-year age cohort over the projection period, by observing the diagonals in the table. It is clear that at first - up to age 25 for the younger cohorts and age 40 for older - the sex ratio will increase for each age cohort. For example, for the cohort aged 0-4 in 1980, the sex ratio will increase from 1043 in 1980 to 1046 in 1985 and 1062 in 2000. This increase occurs because of the much higher loss of females through emigration.

From these ages upwards, however, the sex ratio will decline as the higher mortality level among males offsets the migration sex differential. For example, the cohort aged 35-39 in 1980 had a sex ratio of 850 in that year but this is projected to decline to 835 five years later, and only 676 in 2015.

For the same reasons just outlined, at any given year the sex ratio is higher at earlier than at later ages. Thus, with the single exception of the population aged 5-9, there are more males than females for each 5-year age group in 1980 up to age 20-24.

At higher ages, however, females exceed males and the sex ratio tends to fall as age increases. At later years the projections indicate that males will exceed females to an increasingly higher age; by 2015, it is projected that there will be more males than females among all age groups under 40 years of age.

SAINT LUCIA

2015	436.3	100.4	28.13	431.3	100.4	29.61
Low Variant						

In 1980 males exceeded females only in the age groups 0-4, 10-14 and 15-19 while the sexes were almost numerically equal in the age groups 5-9 and 20-24. The excess of males was not large, there being only about 4 percent more males than females in the group 0-4 with the largest sex ratio. At ages 25 years and over, females exceeded males. This surplus in turn was small in the age group 25-29, but by age 30-34 there were only 860 males per 1000 females, and the sex ratio declined almost consistently, with there being more than twice as many females as males at age 80 years and over.

Because of the changes described above, while the pattern of males exceeding females in the younger age groups, and females exceeding males in the older will continue over the projection period, this dividing age increases.

In the year 2000, for example, males will exceed females up to age 35-39, there will be a virtual equality of the sexes at age 40-44, and females will exceed males at ages 45 years and over. Here again, as throughout the projection period, the excess of males over females will be small, with one exception the sex ratio being under 1050, but the excess of females at the older ages will be appreciable and increase with age.

In considering the special needs of women and the resources that must be provided to meet these needs, this excessive predominance of females at the higher ages must be borne in mind.

Vital Rates

The assumptions of a declining total fertility rate and an increasing average length of life imply that there will be a rapid decline in the crude birth rate (CBR) and a much slower decline in the crude death rate (CDR).

2010-2015	13.05	18.28	5.22	12.77	18.24	5.47
Low Variant						

In each variant, the CBR therefore will fall rapidly during the period that the TFR is assumed to be falling, and will change only very slightly thereafter because of the impact of the age-sex structure of the population. According to the low variant, the CBR which was 33 per thousand in 1980-1985 is projected to fall rapidly to 19 by 1995-2000, and after fluctuating very slightly to end at 18 in 2010-2015. The medium and high variants also end at 18 per thousand by 2010-2015, reaching this level by 2005-2010 and 2010-2015 respectively.

The CDR, which was just over 6 per thousand in 1980 is projected to fall, by the end of the projection period, to 5 in the case of the high variant and very slightly more (5.2 and 5.5 respectively) for the medium and low variants. The CDR is lowest for the high variant because of its younger population.

Infant Mortality Rates

The infant mortality rate (IMR), which was 24 (infant deaths per 1000 live births) in 1980 is projected to fall by one-third to 15.3 by the end of the projection period. Since it is assumed that the average length of life will improve more rapidly for females, the female IMR will also fall more rapidly, from 22 to 12, or to just over one-half, as against a fall from 27 to 19 (i.e. to about two-thirds) in the male IMR.

SAINT LUCIA
TABLE 8.8: INFANT MORTALITY RATES
(PER 1000 BIRTHS)

Five Year Period	Males	Females	Total
1980-1985	26.63	21.54	24.14
1985-1990	24.35	18.30	21.38
1990-1995	22.54	15.88	19.28
1995-2000	21.26	14.13	17.77
2000-2005	20.26	13.00	16.70
2005-2010	19.50	12.17	15.90
2010-2015	18.89	11.56	15.30

Reproduction Rates

The gross reproduction rate (GRR) corresponding to a TFR of 2.1 with a sex ratio at birth of 1040 is 1.03 and this level is achieved in the year that the TFR is assumed to reach replacement level in each variant.

The net reproduction rate (NRR), which takes into account the mortality of females up to and including their childbearing period, will in fact attain virtual replacement level (1000-1004 female births per 1000 female births in the preceding generation) by the time that the TFR falls to replacement level.

However, because of the age structure of the population, with the size of the age cohorts increasing for younger ages, the total population will continue to increase throughout the projection period as indicated earlier.

SAINT LUCIA

IX - SAINT VINCENT AND THE GRENADES

PROJECTION ASSUMPTIONS

Mortality

It is assumed that the average length of life (expectation of life at birth) which was 65.6 years for males and 70.9 for females in 1980 will improve to 70.4 and 76 years respectively by 2010-2015. This implies that the differential between the female and male length of life which was 5.3 years at the outset, will increase only very slightly to 5.7 years by the end of the projection period.

Low	-5000	-4583	-4166	-3749	-3332	-2915	-2500

Fertility

The total fertility rate (TFR) was 3.9 in 1980 and is kept at this level in the constant projection. For the realistic variants, it is assumed that in the first 5-year period 1980 -1985, the TFR will be 3.45 and that it will drop steadily to replacement level (2.1) by 2010-2015 for the high variant, 2005-2010 for the medium and 1995-2000 for the low.

Migration

It is estimated that the country will lose about 1000 persons per year, on average, in the first quinquennium. It is assumed that this number will decline by one-half and then remain constant in each of the three realistic variants. The most rapid decline, for the high variant, assumes that the level of 500 emigrants per year will be reached by 1995; for the medium and low variants, the target year is 2005 and 2010 respectively.

ANALYSIS OF RESULTS

The Total Population

The total population of St. Vincent and the Grenadines in 1980 was 102,800. If the total fertility rate and the number of emigrants remained constant until 2015, by that year the population would have nearly doubled to 202,900.

The realistic variants project an appreciably lower population by the end of the projection period. The 2015 population, according to the high variant, will be 158,500, or 22 percent less than the constant, while the low, at 145,500 would be 28 percent lower.

The projected population, according to the medium variant, will reach 152,100 by 2015, increasing by 1.3 percent per annum until 1995, and then more slowly, the rate of growth after 2005 being under 1 percent per annum.

Low Variant						

The Components of Population Growth

Over the projection period as a whole, the loss of population through emigration is very slightly higher than through death in the case of the low variant. In the case of the medium variant, the number of deaths (26,200) is somewhat greater than the number of emigrants (25,000). For the high variant, deaths exceed emigrants by 4,100.

For the realistic variants, the projected number of births for the whole period is 95,100, 100,800 and 105,000 respectively for the low, medium and high variants. The number of births, according to the constant variant, would be very much higher - 163,600.

If the TFR remains unchanged (the constant variant), the number of births will increase steadily from 17,700 in the first 5-year period to 29,200 in 2010-2015. If, however, the TFR should decline, as is assumed for the realistic variants, the number of births per quinquennium will fall steadily throughout the projection period, with only one exception for each variant. For the high and medium variants the exception is the year 1995, when the number of births will increase slightly; for the low variant the exceptional year is 2005.

Because of the declining mortality rates, the actual number of deaths is projected to fall at first, for each of the realistic variants, but with the growth and aging of the population, there will be an upturn in the number of deaths. In the case of the medium variant, the annual number of deaths is projected to fall slightly from 3,800 in 1980-1985 to 3,600 in 2000-2005, but then increase to 4,000 by the end of the projection period.

As a net result of the changes in the components of growth, the total population growth over the 35-year period is projected to be about 42,900 for the low variant, 49,500 for the medium, and 55,900 for the high. In actual numbers the population growth increases at first and then declines, the turning point being 1990 for the low, 1995 for the medium and 2000 for the high variants. In the case of the low variant there is an upturn again after 2005.

Age Distribution

In 1980, the school-age population (5-14 years) and the population of mature working age (25-64 years) were roughly equal in size, comprising 29 and 28 percent respectively of the total population. Somewhat smaller was the young adult group (15-24 years) - 23 percent. The youngest and oldest age groups (0-4 years and 65+ years) were smaller, with 15 and 6 percent of the total respectively.

According to the realistic variants, the population of mature working age will increase steadily, nearly doubling by the end of the projection period. The oldest group - 65 years and older - will fall marginally from 6 to 5 percent. All the other age groups in the table will fall

* Due to Rounding figures may not add to 100

steadily, the only exception being the young adults group which will increase very slightly between 1980 and 1985. By the year 2015, according to the medium variant, the population of mature working age will comprise 54 percent of the total, the school-age and young adult groups will be 16-17 percent, the pre-school 8 percent and the old-age dependents group 5 percent of the total.

As seen in Table 9.5, both the pre-school and the school-age populations will be numerically smaller in 2015 than in 1980, both groups falling fairly steadily to 82-83 percent of the 1980 size. The young adult population will increase to 15 percent above the 1980 figure within 10 years but will then fall and rise again, being 12 percent above the 1980 figure at the end of the projection period. The old-age group will increase steadily by 22 percent over the projection period. But it is the population of mature working age that will massively increase, the index number for 2015 being 286. The figures given are for the medium variant, but the pattern is the same for all three realistic variants.

2010-2015	83	82	117	318	131	79	77	101	316	130

The changes clearly signify that the major socio-economic problem of the future that will emerge as a consequence of the projected population growth will be the need to provide jobs for the population of mature working age which will be nearly three times as large in 2015 as in 1980. Serious problems of unemployment and under-employment, and the related social and economic problems will be the result, unless the economy can be expanded to offer employment to the rapidly growing labour force envisaged by these projections.

The distribution of the population according to 5-year age groups, by sex, is given in Appendix I. The pattern of this distribution is shown in Diagram 8 for 1980 and for 2015 for each of the realistic variants.

In 1980, the age group 5-9 was very slightly larger than the 0-4 group. At higher ages the pyramid narrows quickly to about age 35-39 and then very much more slowly for older age groups. For the high and medium variants the projected pyramids indicate very little difference between the size of the 5-year age groups up to age 25-29, and a reduction in the next two age groups to age 35-39. The age group 40-44 is somewhat larger, but then the size of age groups narrows slowly to age 55-59 and then more quickly. The pattern of the low variant is quite similar except that the age groups spanning 20-44 years are very slightly wider than the younger age groups.

SAINT VINCENT AND THE GRENADINES
DIAGRAM 8: AGE PYRAMIDS 1980-2015

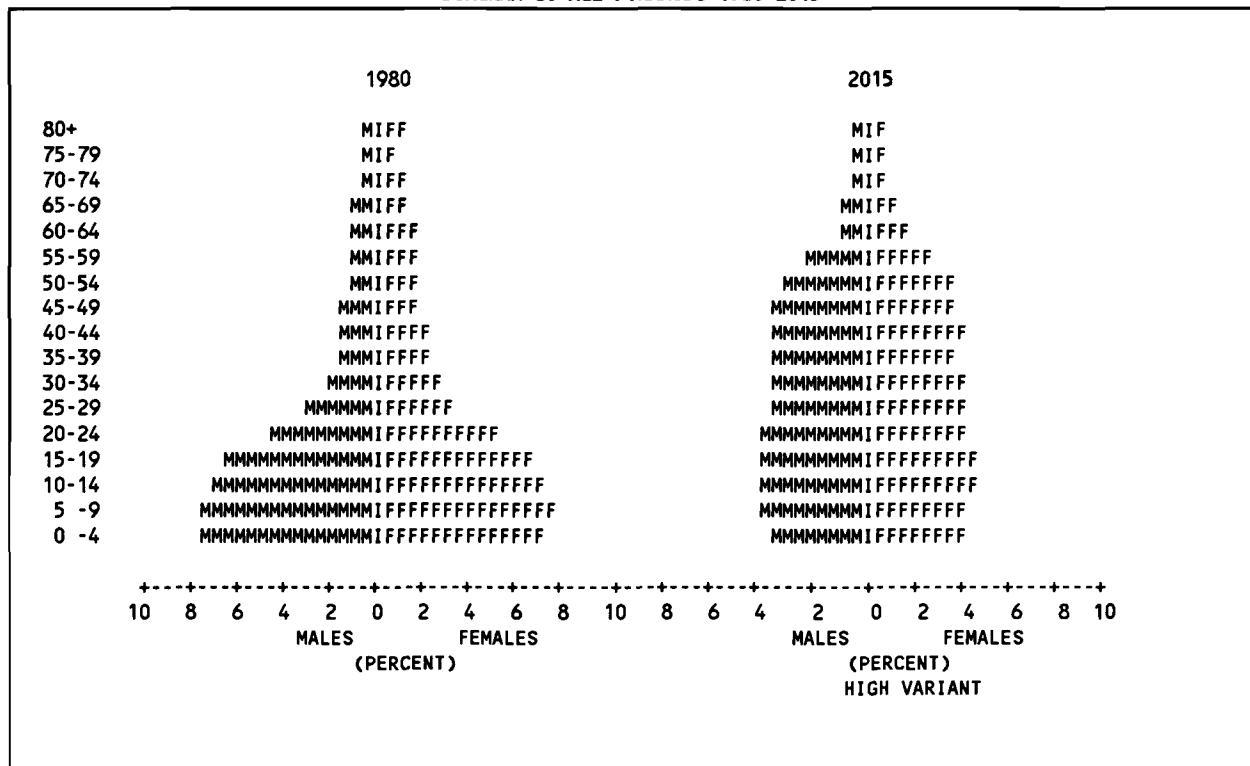

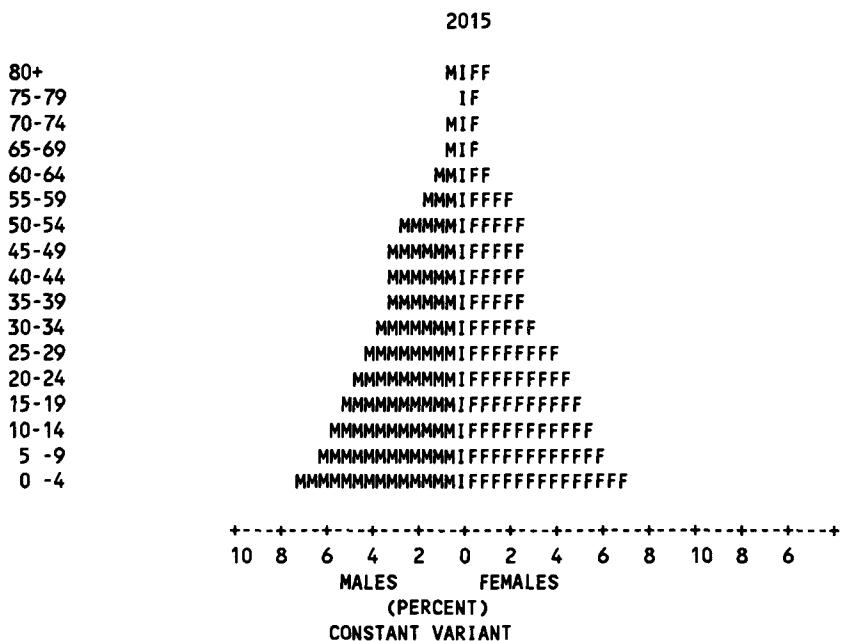

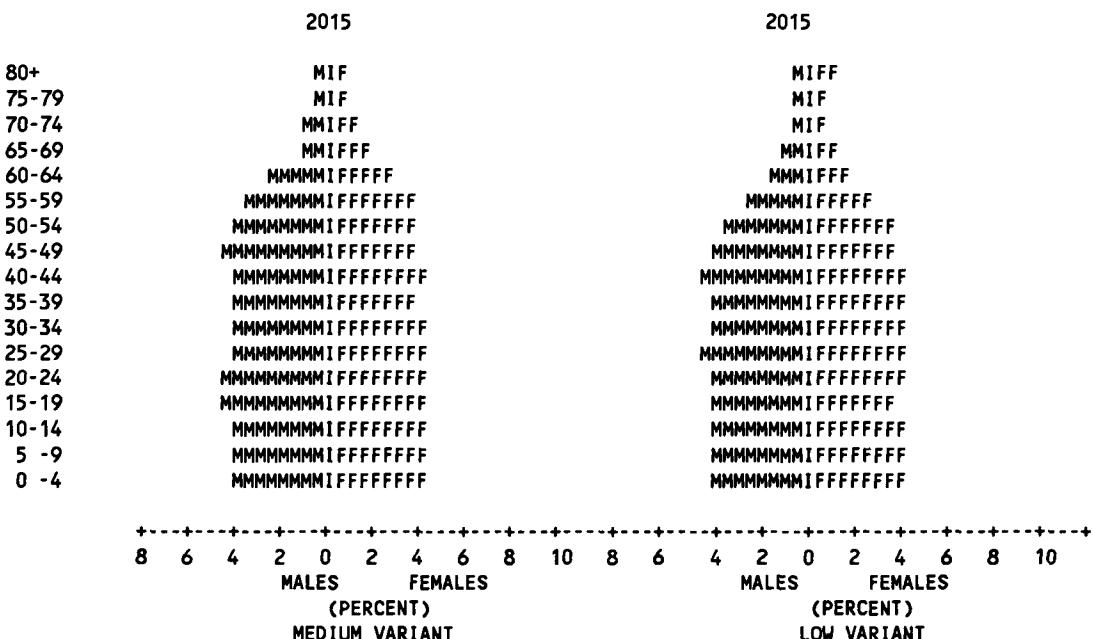

DIAGRAM 8 CONTINUED

Dependency Ratios

The very significant increase in the proportion of the population of working age (15-64 years) implies that the dependency ratio will, in turn, decline significantly. In 1980 the dependency ratio was 981 per 1000 persons of working age. By 2015 it is projected that the ratio will be 412 for the medium, 427 for the high and 408 for the low variant. In all variants the dependency ratio is projected to decline steadily.

2015	412.2	102.3	30.11	407.6	102.6	31.21
Low Variant						

The significance of this declining dependency ratio is that relatively less of the country's resources will have to be diverted to the dependent young and old populations, and hence much more will be available for providing the jobs which, as indicated above, will be urgently needed.

Aging of the Population

The net effect of the changing age structure, and in particular the fall from 44 to 24 percent in the population under 15 years of age, will be an increase in the average age of the population. The median age in 1980 was 17.4 years. According to the medium variant, by the year 2000 it will be 24.4, and it will continue to increase to 30.1 years in 2015. By that year, the median age will be 29.5 years for the high and 31.2 years for the low variant.

Sex Distribution

There were fewer men than women in 1980, the sex ratio being 940 males per 1000 females. According to the projections, this ratio will increase slowly but steadily over the 35 years of the projection, so that by 2015, there will be slightly more males than females (1020).

Appendix II gives the sex ratios by 5-year age groups for all variants. For the medium variant for 1980, males were slightly more than females for the first four age groups, the excess of males being just 3-4 percent up to age 14, and very much less for the 15-19 age group. From age 20 onwards females exceed males, and the excess of females increases with age until at the highest age group (80+ years), there were nearly 3 females for every one male.

But given the high sex ratio at birth assumed for the projections (1050 male per 1000 female births), and the anticipated higher emigration of females, it is projected that the age up to which males will exceed females will continually increase, and by the end of the projection period - 2015 - there will be more males than females in every 5-year age group up to 50-54. It should be noted, however, that the excess of males will continue to be small, not exceeding 8 percent (1078 males per 1000 females) for any age group. On the other hand, at ages 70-74 and higher, females will be considerably more than males, the index numbers ranging from 814 for the 70-74 group to 460 for those 80 years and older.

In large measure the actions that must be taken to improve the situation and the status of women in the society and to maintain such improvements in the future are not related to the numbers of women or the sex ratios. Nevertheless, the above figures indicate that the needs of the older population, and more particularly of the old-age dependents will, in very large measure, be the needs of women who so greatly exceed males at these ages.

Vital Rates

The crude birth rate (CBR) at the outset of the projection period is given as 29 births per thousand population, and the crude death rate (CDR) as 7. The CBR is projected to fall steadily to 17 by 2015, and the CDR to about 5½. The crude birth rate will fall more rapidly, at first, for the low variant and least rapidly for the high. For example, in the period 1995-2000, the CBRs for the high, medium and low variants will be 24, 23 and 20 respectively.

Low Variant						

Infant Mortality Rates

The infant mortality rate - deaths among infants under 1 year of age per 1000 live births - in 1980 was 55 for males, and very much lower - 37, for females. According to the assumed mortality schedule, by the end of the projection period the male rate will have fallen to 30, while the female rate would be just one-half of the male rate. For both sexes together, the IMR will fall from 46 in 1980 to 23 in 2015.

ST VINCENT AND THE GRENADINES
TABLE 9.8 : INFANT MORTALITY RATES
(PER 1000 BIRTHS)

Five Year Period	Males	Females	Total
1980-1985	54.94	36.84	46.11
1985-1990	48.07	30.87	39.68
1990-1995	42.65	26.22	34.64
1995-2000	38.23	22.53	30.57
2000-2005	35.00	19.50	27.44
2005-2010	32.35	17.40	25.06
2010-2015	30.21	15.73	23.15

Reproduction Rates

With the assumed sex ratio at birth of 1050, the total fertility rate of 2.1 (replacement level) is equivalent to a gross reproduction rate (GRR) of 1.02. The GRR at the beginning of the projection period is given as 1.68.

The net reproduction rate (NRR), which takes into account mortality in the female cohorts was 1.59 in 1980-1985 according to the realistic variants. It is projected to be just under 1.0 for all three variants at the end of the projection period, dropping to below replacement level in the year that the TFR is assumed to reach 2.1 for each variant.
